STATE LIBRARY.

When, from whom, and how this volume was obtained,
with the price paid, if any, may be found opposite
the above number in the Register of Books.
which is always open to inspection.

Extract from the Political Code.

SECTION 2296. Books may be taken from the Library by the MEMBERS OF THE LEGISLATURE, DURING THE SESSIONS THEREOF, and by other State officers at any time.

SEC. 2298. The Controller, if notified by the Librarian that any officer has failed to return books taken by him within the time prescribed by the Rules, and after demand made, must not draw his warrant for the salary of such officer until the return is made, or three times the value of the books, or of any injuries thereto, has been paid to the Librarian.

SEC. 2299. Every person who injures or fails to return any book taken is liable to the Librarian in three times the value thereof.

No person shall take or detain from the General Library more than two volumes at any one time, or for a longer period than two weeks. BOOKS OF REFERENCE SHALL NOT BE TAKEN FROM THE LIBRARY AT ANY TIME.—[Extract from the Rules.]

The Foregoing Regulations will be strictly enforced.

MINING AND SCIENTIFIC PRESS.

VOLUME XLVIII
Number 1.

Anderson's Concentrating Mill.

David H. Anderson, of Butte City, Montana, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency, a new amalgamating and concentrating appliance which consists of a series of circularly moving and rocking pans, placed in descending steps, each one receiving the discharge from that above it through suitable gates, chutes and receivers. Peculiar mechanism is adopted to work these pans. The engravings we give herewith represent the pans; and also a whole concentrating mill, the latter being shown by the cuts on pages 8 and 9, and the concentrator itself on this page. Fig. 1 is a side elevation of the concentrating pans. Fig. 2 is a rear view of the concentrator, and Fig. 3 is a plan view.

The pans or bowls, *A A*, to receive the material to be worked have rims projecting inwardly to prevent splashing of pulp. The pans are supported on transverse shafts, *B B*, which extend across beneath them just forward of the center, and their rear sides are supported by vertical rods, *C C*. The shafts, *B*, are secured in boxes beneath the pans, and their ends project so as to be connected with the wrist-pins, *D*. The shafts *F F* support on their ends and rotate disks, *E*, said disks being provided with slots through which project wrist-pins, *D*. The wrist-pins are intended to be adjusted by means of nuts to or from the center of the disks to give a longer or shorter throw to the crank thus formed, and by their movement the pans are given a curvilinear reciprocating motion.

The vertical shafts *F*, to which the disks, *E*, are fixed, extend down to the lower part of the apparatus, and have bevel gears, *E*, *G*, fixed near their lower ends, their ends in steps turning upon the frame work or bed. Transverse shafts extend across this frame-work, and these carry bevel gears, *J J*, which mesh with the wheels, *G*, and thus rotate the vertical shafts *F*, and disks *E*. New shafts may be driven by belt pulleys. Another shaft, *L*, extends longitudinally from end to end of the frame and has cam wheels, *M*, fixed to it beneath the rear portion of each pan. These cams serve to give the vertical rods *C*, an up and down movement, and through them the pans are caused to rock upon their horizontal supporting axes. The drawing shows the vertical movement imparted to the rods *C*, by means of transverse levers *N*, one end of each of which is pivoted to the frames to form a fulcrum, while the other end has the rod *C*, connected with it by a pivoted joint. A roller, *O*, is journaled upon the side of each lever, *N*, in such a position as to be acted upon by the cam, *M*, as it rotates. Only one letter *M* is shown, but there is one for each pan; and the reciprocating motion there imparted to the levers is transmitted to the rods, *C*, and through them to the pans. The rods, *C*, are attached to the rear of the pans by a swiveling connection, *P*, allowing the rods to raise and lower the rear of the pan without interfering with any of its other movements. Each of

the vessels, *A*, has a chute or receiver, *P*, upon its upper side and a distributor, *Q*, upon its lower side. The receiver on the first pan is supplied from the battery or other crushing or pulverizing apparatus through suitable connecting chutes, and the receivers of the follow-

a receiver *U*, so that the concentration may be led to any desired point.

The operation is as follows: The pulp is let into the upper pan and distributed and settled by the peculiar motions imparted to it, the heavier particles settling to the bottom, and

will be again settled, and so on to the end of the series, so that the different grades and values will be separated at one operation.

In some cases it is desirable to give the pans a parallel circular motion: in others a compound circular motion, by means of the horizontal disks and crank or wrist pins. The latter movement is effected by means of another set of gear wheels upon the horizontal transverse shaft, and upon the opposite side of the gears *G*, from *J*. Both these gears *J*, and the others have feathers in the shaft so they are connected or disengaged. When the gears on the same side relatively meet with their corresponding gears *G*, the movement of the gears *G* will be in the same direction, and the pan will be given a single circular motion about the center of the wheels *G*; but if the two inside gears are engaged with *G*, it will produce a movement of these gears in opposite directions and give the pan a compound motion.

The object of the parallel circular motion is to move the vessel equally in all directions, thereby imparting to the pulverized ore, sand and debris an even movement as they pass over or through the vessel. The object of the compound circular motion is to agitate the passing material mostly in a sidewise or oscillatory manner around the center of the pan, while creating but little motion in the direction in which the material flows across the vessel. This movement is especially useful for saving the lighter metals, and gives the machine a better settling action than what Mr. Anderson terms the "parallel motion."

The drawings show Mr. Anderson's device as arranged by him. In some cases he puts hoppers inside of the pans on the receiving side, and above the level of the material to be worked, instead of being attached to the outer side, so as to shorten the machine. Mr. Anderson, with one of these machines, took out of the mill tailings of the Burlington mill, near Butte City, in ten days' running and experimenting, 4,000 ounces of silver, 27 tanks of quicksilver, and 90 tons of concentrates, assaying 98 ounces silver per ton and 65 per cent carbonate of lead. The machine worked at the rate of five tons per hour. Mr. Anderson is a practical mill builder and mechanical and mining engineer. This is not his first invention in the line of metallurgical appliances.

The machines are run in combination with stamp batteries for gold amalgamation and concentration. The mode of operation is to add mercury in the mortar of the battery; close the valve of the upper pan of the machine and charge with sufficient mercury to cover the bottom of the pan, so as to amalgamate the free gold.

Then concentrate the sulphurets and metals from the ores with the two lower pans, regulating the valves in the bottom of the pan for continuous discharge, or at intervals if these ores have not much "concentrates."

For working mill tailings the machines are run by portable engines, and supplied by electro-

REAR VIEW OF CONCENTRATOR.

PLAN VIEW OF CONCENTRATOR.

ing pans are supplied from the distributors of those preceding them. Long slots open from the receivers into the pan, and similar slots open from the opposite sides of the pan into the distributors. The material is thus evenly distributed over the bottom of the pans.

Each pan is provided with one or more valves or gates in its bottom. These valves are operated by levers *T*, by which the amount of opening and rate of discharge may be accurately governed. Beneath the discharge openings is

the lighter arranging themselves above and flowing through openings at the side into the distributor, and thence into the next pan.

If it be desired to amalgamate the free gold and silver at the same time that the concentration is being accomplished, mercury may be put in one or more pans. The heavier metals—gold, silver and mercury—will thus remain at the bottom of the first pan, and the lighter metals will be discharged through the distributor *Q* into the next pan, where the heavier

CORRESPONDENCE.

Precipitation of Gold.

EDITORS PRESS:—In the PRESS of November 3d, in C. H. Aaron's article on "Precipitation of Gold," he writes as follows: "It appears, however, that the gold terchloride causes oxidation of both the copper and sulphur, and it will be readily seen that gold in the presence of a copper salt may be precipitated in metallic state, and but little contaminated by copper sulphide, by means of hydrogen sulphide, and may be further purified by washing in a bath of fresh solution of gold." Also, in the appended paragraph: "If their leach contains copper it seems possible that hydrogen sulphide might cause the same trouble"—i. e., formation of sulphuric acid and consequent precipitation of lime as sulphate.

Judging from accepted methods in standard schemes of chemical analysis, and from carefully performed experiments, I venture to assert that he has drawn incorrect conclusions. I would thus respectfully lay the matter before the readers of the PRESS.

If sulphuric acid were formed, and gold precipitated as metal in treating the solution with hydrogen sulphide, two very serious defects must exist in Fresenius' system of analysis. (a) Barium and strontium would be precipitated as sulphates by treatment with hydrogen sulphide in presence of gold and copper, and would not be found in their proper place. (b) The metallic gold would not dissolve in ammonium sulphide, thus failing of detection. I refer to Fresenius. See his Qualitative Analysis by Johnson, p. 369. This is directly contrary to Mr. Aaron's statement.

In order to verify this experimentally, I prepared two solutions containing both gold and copper, one by means of aqua regia, the other by chlorination. Both were treated with hydrogen sulphide to saturation. Had sulphuric acid been formed, it would have remained in the solution. After filtering barium chloride failed to reveal any trace of sulphuric acid in either solution. Had the gold been thrown down as metal it would have failed of solution in ammonium sulphide. After thoroughly washing the hydrogen sulphide precipitate with yellow ammonium sulphide, not a trace of gold could be found in the residue, while it was found in the washings; thus showing that the gold must have been precipitated as sulphide.

I conclude that hydrogen sulphides precipitates both gold and copper as sulphides, neither one as metal, and that no sulphates are formed. Indeed I can not conceive how this oxidizing action could obtain in the presence of so powerful a reducing agent as hydrogen sulphide.

No fear of trouble with lime in the leach need be entertained when hydrogen sulphide is used to precipitate the gold. But the copper also goes down with the gold, though, perhaps, as Mr. Aaron says, it may be replaced by metallic gold upon washing with fresh gold solution. In this case I can readily imagine the sulphur and copper as being oxidized by the gold terchloride, free hydrogen sulphide being absent. I have not experimented upon this.

Ferrous chloride is doubtless the best precipitant to use in presence of lime, as neither the latter nor copper would be precipitated, while the metallic state of the gold renders subsequent roasting needless.

Mr. Aaron states in the same article that proto-chloride of manganese answers for precipitation of gold. I take issue with him upon this point. I not only find that the proto-chloride free from iron fails to precipitate gold, but that the per chloride actually chlorinates metallic gold, bringing it into solution as chloride, and becoming reduced meanwhile to proto-chloride. Indeed the perchloride spontaneously evolves chlorine and becomes the proto-salt.

The waste liquor from the chlorine generator contains an excess of acid and some iron as per salt, both of which may be utilized by addition of scrap iron. But when this is used for precipitation the iron is the reducing agent; the manganese remains inactive.

Were manganese available, as he states, it could be used alternately for precipitation and chlorination, thus reducing cost of gold leaching. Signal, Arizona. N. A. BOLES.

MINING IN FRANCE.—The greater portion—two-thirds—of the total annual production of coal in France comes from the northern coal districts of the Nord and Pas de Calais, and from the basin running southward through the departments of the Loire, Rhone, Ardeche, and Gard to the Gulf of Lyons. The production amounted to 21,000,000 tons in 1882, which is less than one-seventh that of Great Britain, less than half the production of Germany, and about one-quarter that of the United States. As early as the eleventh century the coal mines of Saint-Etienne were known, but were not worked to any great extent until the Revolution. The northern coalfields were discovered in 1847. The consumption of coal in France last year was about 10,000,000 more tons than she produced. Although large quantities of iron ore is imported by France, the country is rich in iron mines.

THE Iron Mining Company, of Hotelling, has purchased the iron mine in Shasta county, near the United States Fishery.

Manganese.

Sources.

Manganese is found in deposits of various oxides extending through the Atlantic States from Maryland to Georgia. The mines furnishing the most valuable ore at present are located in the "Etowab region" in Bartow county, Georgia. From 500 to 1,000 tons are here mined annually, and while this is less than is produced in Virginia the higher percentage of manganese in the Georgia ore makes it a more important feature of the total supply. The deposits in Virginia rank next in importance. The mines are numerous and furnish a total of from 2,000 to 3,000 tons. One mine alone in Augusta county yields 1,500 tons annually. These two sources are the only ones which enter into the manganese industry to any extent. The information concerning them was furnished by Mr. C. L. Oudsluys. There are large deposits of ore at Warminster, on the estate of Mr. Philip Cabell, in Nelson county; and also in Rockingham and Campbell counties. Near Harper's Ferry, in Jefferson county, West Virginia, there is a mine which was formerly worked, and ore is again met with in the northwestern part of this State. There are deposits in North Carolina, but of such hard quality that it is not profitable to work them. Greenville, South Carolina, has furnished a small quantity to the trade, but the quality, like that of the Virginia ore, is too poor to render it of much value. The same is true of more extensive deposits in Tennessee, where, in spite of a few exceptionally rich veins, the ore falls below the average.

The ores of manganese have been observed at many different places on the Pacific coast, the heaviest deposits yet discovered, or at least opened up, being on Red Rock, a small island in the Bay of San Francisco, 10 miles north of this city. Information regarding this occurrence is furnished by Mr. C. G. Yale. This island contains 27 acres, and rises to a height of 250 feet above the water. The ore, which is of the gray variety (pyrolusite), occurs in large masses, distributed through a black, flinty gangue, a heavy belt of which extends for seven or eight hundred feet across the island. The exploratory work here consists of a tunnel, which intersects the ore channel at the depth of 200 feet, and several drifts run and pits sunk on it higher up. This work was done in 1866, at which time over 200 tons of ore carrying 70 per cent binoxide were extracted and sent to New York with a view to testing its commercial value. As this lot sold for less than freight and commissions, the work of ore-extraction was discontinued and has not since been resumed. The cost of taking out the ore and delivering it in San Francisco amounted at that time to \$10 per ton. As this is twice as much as the same service would now cost, and there is likely to grow up some demand for manganese for local uses, there is a probability of this mine again being worked at an early day.

Many other occurrences of pyrolusite, said to be in workable quantities, are reported but not utilized, in the Far West. In the Mammoth district, Nye county, Nevada, occur a large deposit of the tungstate of manganese.

Small quantities of very pure manganese dioxide are imported from Nova Scotia, for use in neutralizing the green tint imparted to flint glass by minute traces of iron. The Nova Scotia ore is remarkably free from iron, and hence its value in the glass industry. Sulphate and chloride of manganese and potassium permanganate are the only other salts which have thus far found any industrial application in the American arts. Permanganate is imported in small quantity from Germany, and is worth from 50 to 70 cents per pound in this country. It is safe to prophesy that in the near future another salt of manganese—manganate borate—will be largely used in the United States, as it already is in Germany, Austria and France, for hoiling with linseed oil and fine varnishes. According to the most experienced varnish manufacturers, manganate borate offers an aid in making driers, superior to that of any other substances.

Character of the Ores

The three prominent ores of manganese are: 1, black oxide, or pyrolusite (MnO_2); 2, braunite, or brown oxide of manganese (Mn_2O_3); 3, manganiferous iron ore. It is very rarely, if ever, the case that the ore is found in a state of purity approaching the composition of a definite mineral. It is usually a mixture of black and brown oxides of manganese and ferrous and ferric oxides of iron, in varying proportions, and the commercial name given is intended to designate the predominating feature of the ore. If, as is sometimes the case with Georgia ore, the amount of manganese reaches the neighborhood of 80 per cent, and the substance shows some crystalline form and is soft, it is called by the proper mineralogical name, "pyrolusite." But ordinary ore containing less than 75 per cent of MnO_2 is called "black oxide" of manganese. If, however, the amount of manganese dioxide runs as low as 20 to 30 per cent and oxide of iron becomes the dominant ore, it is called "manganiferous iron ore." Black oxide is the only manganese ore mined in this country, and if the manganese dioxide in it falls much below 60 per cent, it is not worth bringing to the market. It may be said that the Virginia ore usually contains about 60 per cent, while Georgia ore runs from 66 to 70 per cent. The manganiferous iron ore

found in the United States usually contains phosphorus, sometimes to the extent of one to two per cent. Even five one-hundredths of one per cent of phosphorus renders steel "cold short" (that is, brittle when cold), and this more than counter-balances the beneficial effect of adding manganese in the manner stated later in this notice. A few other substances are always present in the ores, as is shown by the following table of analyses of samples from the places named:

Analyses of Black Oxide of Manganese.

	Georgia Ore.	Ore from Campbell Co., Va.
Water.....	1.17	1.05
Silica.....	4.00	21.76
Manganese dioxide.....	66.40	57.60
Ferric oxide.....	10.08	9.93
Barium sulphate.....	.29	1.05
Calcium carbonate.....	trace	.85
Oxides of manganese other than dioxide.....	18.06	7.76
Total.....	100.00	100.00

Quantity Mined.

The total quantity of manganese ores mined in 1882 was very nearly 3,500 tons (of 2,240 pounds). Its spot value at the mines is \$11 to \$20 per long ton, according to the percentage of manganese. The cost of mining is from \$5 to \$10 per ton.

Utilization.

The chief use of manganese ores is as a ready and easily available source of oxygen. For this reason the dioxide is the only valuable constituent, because it can be made to give up its oxygen by several means. Advantage is taken of this oxidizing power of the dioxide in the preparation of chlorine and bromine. It is extremely difficult to separate these elements from other elements with which they are ordinarily in combination. It is a simple matter, however, to obtain hydrochloric acid; and when manganese dioxide is added to this, its oxygen unites with the hydrogen, forming water, and leaves part of the chlorine free. As it is very difficult to transport chlorine in its ordinary gaseous state, it is passed over slaked lime, and thus made into "bleaching powder," which is a mixture of chloride and hypochlorite of calcium. Bromine is made by a similar process, but as it is a liquid, it is not necessary to convert it into a substance analogous to bleaching powder. These processes, which consume probably three-quarters of the manganese mined in this country, are carried on at several places near Pomeroy, on the Ohio river, and at a few other points in the United States. Where manganese ore richer than 70 per cent is obtained, it is usually found profitable to send it to England for the manufacture of bleaching powder, and a small proportion of the yearly supply is thus annually exported. This is the only case of the exportation of manganese. Manganese ore is also used as an oxidizing agent in boiling linseed oil and varnish. When linseed oil is boiled with powdered manganese dioxides, the oil takes up a certain amount of oxygen and becomes thick, drying rapidly. It is doubtful whether the manganese dioxide does more in this case than to expose a greater surface of the oil to the oxidizing effect of the air, for the mineral does not appear to lose its efficiency after continual use. Manganese dioxide is also used in the preparation of oxygen, but only when mixed with chlorate of potassium; because manganese dioxide requires a very high temperature when heated alone before it will give up its oxygen. When heated with potassium chlorate the latter yields its oxygen at a comparatively low temperature, the dioxide serving only to distribute the heat through the mass.

So far as can be ascertained, these are the only uses for which the native ores of the United States are at present available. There are two or three uses into which the manganese itself enters; but, for these, foreign ores are used altogether. Considerable quantities of manganiferous iron ore are imported, principally from Carthage, Spain. The ore is brought as ballast in sailing vessels and steamers coming to American ports in search of cargoes. Probably the largest amount comes to Baltimore, but some is also received in Philadelphia and New York. The following table gives the importations of manganiferous iron ore received in Baltimore during 1882. The percentage of manganese is also stated:

Date of Arrival.	Amount, Tons.	Metallic Manganese, Per cent.
April 25th.....	800	17.10
April 28th.....	800	5.93
July 15th.....	2,800	12.84
July 22d.....	800	3.77
August 16th.....	2,000	12.66
August 30th.....	2,000	15.75
September 4th.....	900	15.85
October 10th.....	2,000	15.83
November 28th (in bond).....	4,000
December—(in bond).....	1,000
Total.....	17,100

The imported ore contains an average of about 20 per cent manganese dioxide, so the ore which enters this country is about equal to that mined here. This form of ore is all used in making a superior variety of steel. It has been found that when a small quantity of manganese—less than three per cent of the steel to be melted—is added to steel in the melting pot, inferior steel may be raised to a high grade, and is made capable of welding with iron. This was discovered in 1829 by Mr. Josiah Marshall Heath, who proposed the addition of manganese dioxide with enough charcoal for its reduction to the steel to be melted. (a)

This method of improving steel has since

been introduced into the Bessemer process; but instead of adding manganese dioxide itself, an iron ore containing considerable manganese is used as the starting point. Nearly all the manganiferous ore imported is sent directly west to the Pittsburgh region, particularly to the Edgar Thompson Steel Works.

Since the greater quantity of imported manganese ore comes directly to Baltimore, and moreover, because of the convenience offered to Southern producers of selling ore through Baltimore agents, that city has come to be regarded as the headquarters of the manganese industry, although very little of the ore is actually consumed there.

(a) J. S. Jeans, "Steel, its History, Manufacture, Properties and Uses," 1880, p. 27.

Preparation of Ore for Assay.*

All ore assays must be finely powdered, but not the whole of a large sample need be so. A large sample is broken by hammer and block, pestle and mortar, etc., so that no one piece shall be a considerable fraction, say more than one-thousandth of the whole, then mixed on a suitable cloth or smooth table. The sample is then spread in a layer, and divided, by the back of a saw-blade, a trowel, or spatula, into quarters. Two opposite quarters are rejected and again mixed, after further pulverizing, if needful, and again divided. When reduced to a pound or so, the sample is passed through the coarser sieve, and now a sheet of strong paper or of oilcloth is suitable to mix on, by lifting an edge and drawing it forward so as to roll the sample upon itself, and to heap it in the middle; then again spreading by the spatula, and so several times. The sample is thus gradually reduced in quantity, being more finely ground step by step, until several ounces have passed through the finest sieve.

For mixing a sample, after it has reached a certain fineness, no implement is equal to the finger. Heap the ore, then, with the finger, beginning at the center of the heap, trace a spiral to the edge and back to the center. Again heap by lifting the edges of the sheet, and again spread by the finger, and so on.

Without perfect mixture at each stage of division, the final sample will not be a true one, and this final sample must again be mixed, in order that each assay taken from it may also be a true sample of the whole. An idea of what is required may be got by adding a little flour to a finely powdered sample of dark-colored ore, or charcoal to a light-colored one, and mixing until the tint is uniform without streaks or spots.

Each time that a sample is ground or sifted the whole of it must pass through a sieve unless there are particles of tough matter, such as metal, or silver-glance, etc., which cannot be ground to a powder. In this case the tough matter must be kept, and no further division of the sample can be made, as it must all be weighed and treated as directed further on.

Damp ore must be dried. In particular cases all samples, whether they appear damp or not, should be dried after being powdered, then allowed to cool before weighing the assay. Many substances, such as clay, for instance, lose more and more water at successive degrees of heat up to whiteness, wherefore there must be a standard temperature for the drying. That standard is the heat of boiling water; hence the sample is dried on the water bath.

All implements used in powdering and sifting must be cleaned, lest the sample be contaminated by some remains of a former one. In many cases simply wiping the mortar, etc., with a cloth will suffice, but after rich ore, the tools must be cleaned by grinding some barren quartz, sand, or glass. Sieves are cleaned by brushing and tapping.

The prepared sample is put in a sample pan with a tag on which is marked the number of the sample, and any other desired particulars, such as the general character of the ore, as a guide in dressing or the metal for which it is to be assayed, etc.

The character of the ore can, in general, be ascertained sufficiently and most conveniently by an examination of it in the lump before grinding. When this cannot be done, as in the case of samples which come already ground, recourse must be had to washing (panning) a little of the powder in a dish, by which the character and proportion of sulphurets may be judged, if there are any. The color and general appearance also furnish indications, or special tests may be applied, some of which are given further on.

*This extract is from a plain practical work on "Assaying," by Chas. H. Aaron, lately issued and for sale by Dewey & Co., S. F. Price \$1.

OCEAN STEAMERS.—The increase in the speed of ocean steamers has come to be a matter of great interest. The Alaska and the City of Rome have repeatedly crossed the Atlantic in less than seven days. There are several other vessels whose speed is but little less. Two new steamers are to be added next year which promise to reduce the time of the passage to less than six days.

MINERS' wages in Germany average from \$12 to \$15 per month. In Mexico they average \$18 and \$20 per month, and in Colorado they average from \$2 to \$4 a day—from \$90 to a \$120 per month. Miners wages in Nevada and Northern California are \$4 per day. In El Dorado and Placer counties they are from \$2 to \$3.50 a day.

MECHANICAL PROGRESS.

Heat Developed in Forging.

M. Tresca, of Paris, the well known French experimenter, recently presented to the French Academy of Sciences the results of some very interesting work on the development and distribution of heat produced by a blow from a steam hammer in the process of forging. M. Tresca, in carrying out his experiments, used a carefully polished bar and covered it on both sides with a thin layer of wax. It was then placed on an anvil and struck by a monkey of a known weight, P, falling from a height, H. The faces of the monkey and the anvil were exactly alike, and care was taken that the whole work—namely, P H—should be expended upon the bar. A single blow was sufficient to melt the wax over a certain zone, and this indicated clearly how much of the lateral faces had been raised by the shock to the temperature of melting wax.

As to the form of the zone of melting, it was found always to extend around the edges of the indent produced on the bar by the blow. On the sides of the bar the zone took the form of a sort of cross with curved arms, the latter being thinner and thicker according to the greater or less energy of the shock. With regard to the ratio between the heat developed and the energy of the blow, it was found to be much greater than had been expected when the other sources of loss were taken into account. In some cases this reached 80 per cent, and in a table given by M. Tresca the limits varied for an iron bar between 68.4 per cent with an energy of 288 foot-pounds, and 83.6 per cent with an energy of 648 foot-pounds. With copper the energy was found to be very nearly constant at 70 per cent. The proportion above referred to was less when the energy was less, and also diminished with the section of the bar, this being, no doubt, due to the fact that the heat in this case is conducted away more rapidly. On the whole, M. Tresca sums up his results as follows:

1. The development of heat depends on the form of the faces and the energy of the blow.

2. In the case of faces with sharp edges, the process described allows this heat to be clearly indicated.

3. The development of heat is greatest where the shearing of the material is greatest. This shearing is, therefore, the mechanical cause which produces the heating effect.

4. With a blow of sufficient energy and a bar of sufficient size, about 80 per cent of the energy re-appears in the heat.

5. The figures formed by the melted wax give a sort of diagram showing the distribution of the heat and the character of the deformation in the bar.

6. Where the energy is small the calculation of the percentage is not reliable.

So far we have spoken only of cases where the anvil and monkey have sharp faces. Where the faces are rounded the phenomena are somewhat different. Instead of commencing at the edges of the indent, the fusion begins near the middle, and appears in small triangular figures, which gradually increase in width and depth until at last they meet at the apex. The explanation is that with the rounded edges the compression at first takes place only in the outer layers so long as the blows are moderate in intensity.

New Method of Making Chrome Steel.

Mr. Arthur Armitage, of Sheffield, England, has invented a new process for the manufacture of chrome steel, which, he claims, gives rise to greater hardness, toughness and ductility than is ordinarily obtained. His method is to add from 1 to 2 per cent of chromium into the molten metal, either in the form of manganiferous chromisen, or chrome-spiegel, or in both such forms, the name given being dependent upon the quantity of silicon and graphite contained in the alloy, which in either case is to contain, in addition to the usual proportions of spiegel, 1 to 10 per cent of chromium. These alloys may be obtained by smelting in the blast furnaces mixtures of manganiferous iron ores and chrome iron ores together with lime and alumina compounds, so as to produce a highly basic slag, and thus prevent loss of chromium, an excess of manganese being also used to prevent the chromium slagging out. If the product be manganiferous chromisen—that is, an alloy containing a certain percentage of silicon and graphite—it is mixed with the requisite proportions of pig iron and melted, and the molten mixture converted into steel in the ordinary manner. The manganese present in the metal, it is anticipated, will prevent partially or totally the oxidation of the chromium during the conversion of the metal into steel. If the alloy obtained should contain such small proportions of silicon and graphite as will render it uninjurious if added directly to the metal when in its molten state in the converter furnace or ladle, then the alloy may be used alone or mixed with ferromanganese or spiegel, either in the solid state or run into the converter furnace or ladle after melting, and whether or not chromium has already been introduced into the metal by the use of manganiferous chromisen or otherwise, by this process oxidation will be avoided, and the whole or greater portion of

the total chromium contained in the chrome spiegel will be found in the steel.

IMPROVED WIRE-ROPE ATTACHMENTS.—A simple but very useful invention has lately been brought out in England which may ultimately come into considerable use among miners. The invention consists in an improved method of fastening together wire rope. An old form of fastening was the use of conical thimbles in which, after the end of the rope was inserted, the diameter was conically increased by bending the wires, by driving spikes into the core of the rope, or by casting hot metal round it; in other cases the ropes have been pressed together by bolts and nuts, eccentrics, levers, etc. All these arrangements allow a more or less axial strain to take place, and have the defect of weakening the rope chiefly, and in the greatest degree, at the entrance to the thimble; and, therefore, some of the wires at this place are quickly destroyed, nipped off, or worn through successively. Also in the old modes of splicing, etc., the success depends on the skill of the workman, and even when most skillfully performed the rope suffers a great deal, because through untwisting and otherwise dealing with the rope the positions of the wires and strands to each other are altered, and, therefore, the attachment of the same becomes unequal. Casting hot metal round the rope has the defect of altering the nature of the material. The method of fixing is extremely simple. The end of the rope is pushed into the thimble from the lower part; then on each side of the thimble a wedge is inserted from the top end, and driven in by a few blows with a hammer; the further tightening then ensues in a self-acting manner, as soon as the load is put on the rope. In order to keep the wedges in their proper place, a cotter pin is pushed through a hole at the side of the thimble. When wishing to loosen or detach the rope, a few blows on the loop of the thimble will suffice to make the wedges come up. It is claimed that these improved rope attachments are equally well adapted for metallic or hemp ropes, as well as for flat and round mining ropes, and for tension bars in roof constructions they have proved very efficient.

TEACHING RUSSIA TO MAKE ARMOR PLATES. Sheffield has taught France and Germany how to compete with England in the making of armor plates. She is about to do the like in respect of Russia. Messrs Charles Cammell & Co. have completed with the Czar's government a contract to manage the new works at Kolpino, near St. Petersburg, where what is commonly known as "ship plates" of both iron and steel will in the first place be manufactured. From a patriotic point of view, the action of the English house is somewhat severely criticised; but "limited liability companies" do not usually lay claim to patriotism as one of their assets. From a business point of view the Russian rolling contract looks like the history of the "goose and the golden eggs" repeating itself. But outsiders are not competent critics, and it may be that the armor plate monopoly shows signs of cracking, and that Messrs. Cammell think it better to roll plates for hire rather than not roll at all. Even after a five years apprenticeship under Messrs. Charles Cammell & Co., it is very problematical whether the Russian will be able to produce armor plates at Sheffield prices; but whatever the cost, the Kolpino mills will probably execute all the Russian government work.

A NEW AND ECONOMICAL BELTING.—A foreign exchange reports that the latest patent in bands used for machinery is one for an invention by which it is claimed the only good belt made of textile fabric can be produced. It is not affected by change of temperature, stretches very little, is thoroughly waterproof, is as durable as leather, and being without the objectionable joints and splittings of a leather belt, it runs straighter and truer. The belt is made solely of the best Russian flax, and in price is from 25 to 60 per cent cheaper than leather belting. The unusual strength of the belting results from its being folded somewhat peculiarly, and which also accounts for its stretching so little. It is rendered waterproof by an entirely new process known only to the Russian government, the peculiarity of which process gives it a marvelous grip of the pulley, and, no matter how long it is used, this never leaves it. The flax belt has been in use in Russia for more than two years and a half, and it has given the greatest satisfaction.

AMERICAN CUTLERY.—A correspondent of a London paper, in a recent issue, says: "About the only advantage English cutlery can claim over American competitors is that which attaches to the traditional reputation. It is a mistaken notion that the former have an advantage over the latter in the matter of steel. American steel made for cutlery and tool purposes is as good as any steel made in Great Britain, and it would be folly to question the fact. The art of steel-making has been brought to great perfection in Pittsburgh; and while it is true that some old houses consuming steel prefer and use the English, it is as much because they are unwilling to make any change in material and methods as because they consider English steel really better." While thus admitting the excellence of our material, this writer says that in "finish" our best specimens of cutlery are certainly unsurpassed by the choicest goods of Sheffield.

SCIENTIFIC PROGRESS.

Interesting Experiments with Hot Gases.

In November last, Dr. Werner Siemens presented to the Berlin Academy of Sciences a paper from which it appears that gases heated to a temperature at which steel begins to melt do not emit any luminous rays, if proper care has been taken to subject them only to heating and not to chemical action. Dr. W. Hittorf, of Muenster, has since then recalled the fact that he made observations of this kind in 1879. When causing the electric spark, produced by the 1,600 cells of his battery, to pass between two platinum electrodes, he noticed the positive terminal surrounded by a yellow red light and the negative by a blue glow, but the rarefied gas between the terminals was quite dark, although hot enough to melt any metal rod held in it.

Dr. Siemens' investigations induced Dr. Hittorf to repeat his experiments, employing two iridium bars (of equilateral section with a side of three millimeters and six centimeters long) from the well known platinum works of Mr. Matthiew. These iridium electrodes Dr. Hittorf fixed in strong brass rods, and placed them opposite one another in a glass tube of six centimeters length. By arranging his powerful battery of 2,000 cells in groups so as to decrease the interior resistance, Dr. Hittorf obtained most beautiful and curious effects, the anode melting, and the cathode maintaining its sharp edges; both, however, at white heat, while the gases—nitrogen, hydrogen, and carbonic acid—were experimented with—remained perfectly dark.

From these experiments it would follow that wherever a gas is perceived to be glowing, we have to deal with a combustion or other chemical combination, and not with heat effects only; and it has been established by Mr. G. Wiedemann, that the splendid luminous phenomena of the Geissler tubes are of the nature of a phosphorescence—that is to say, of a slow combustion. That only flames and not heated gases are luminous, may strikingly be proved by a very simple experiment. If a cylinder of very fine platinum foil is suspended in the hottest part of the flame of a Bunsen burner in a horizontal panel, and looked at from a distance through a narrow tube, the platinum cylinder will of course at once begin to glow, but the air within appears dark.

The earliest observation of this kind was probably made by Wedgwood, who as early as 1792 pointed out in the Philosophical Transactions that a current of air blown through a strongly heated clay tube bent in zigzag shape did not emit any light. But the fact appears to have become quite forgotten, although Melloni, the foremost investigator of his time in the field of radiation, clearly distinguished in this sense between heated gases and flames.

Peroxide of Lead as an Insulator.

Having had occasion for a year to apply, for the decoration of articles of jewelry, the procedures pointed out by Nobili and Becquerel for obtaining coloration by means of baths of alkaline plumbates and ferrates, I observed that the articles thus colored became absolutely proof against all galvanic action; that is, their surface when once coated with peroxide of lead or of iron were insulated, and no longer conducted the electric current. A wire of copper, brass, or even iron, may thus be coated with an insulating layer like a stratum of resin or gutta-percha.

This principle, I believe, admits of easy utilization in preparing wires and cables for use in telephony and telegraphy.

The method of obtaining this insulating stratum is, from an industrial point of view, very practicable, and the cost trifling. The hardness of this coating, which resists all atmospheric action, is a guarantee of its durability. The insulation is absolute.

The method of preparation is very simple. A bath of plumbate of potash is prepared by dissolving 10 parts of litharge in 1,000 parts of water, to which have been added 200 parts of caustic potash, and boiled for about half an hour. It is allowed to settle, decanted, and is then ready for use. The wire to be coated with peroxide of lead is attached to the positive pole, and a small platinum anode to the negative. Finely divided metallic lead is precipitated upon the negative pole, and the wire is coated with peroxide of lead, which passes successively through all the colors of the spectrum. The insulation is complete when it takes a brownish black color.

The wire thus covered is perfectly insensible to electric action. Articles perfectly cleaned may be attached to it, and connected with the negative pole of a gilding, silvering or nickeling bath without the current, however powerful, producing any action upon the objects to be coated. Such a wire, if placed in a circuit, and brought in contact with another wire in connection with a galvanometer, leaves the latter entirely unaffected.—*M. C. Widemann, in Comptes Rendus.*

VOLCANIC ASH—WHAT IT IS AND HOW PRODUCED.—Every careful reader has read much of volcanic ash; but there are many who have

very little idea of what it is or how it is produced, only that it is ejected from volcanoes. Whenever a volcano is in active eruption, red-hot lava, in masses of many tons' weight down to the size of small pebbles, are thrown upward with great violence. These pieces, in their descent, encounter other pieces in their upward flight, and by thus crashing together many of the flying pieces are broken and much of the mass is reduced to impalpable dust, the latter of which is borne away by the wind and spread broadcast over the country, often for hundreds of miles distant. At the great eruption of Tomboro, on the island of Sumbawa (east of Java), which continued from April 5, 1815, to the beginning of June, some of the dust thus formed traveled to Tara and Celebes, a distance of 300 miles, and caused a darkness described by Sir Stamford Raffles as more profound than that of the darkest night. This dust was deposited over an area estimated at about two thousand miles in circumference, and in some places was so deep as to do serious mischief. This, of course, is an extreme instance, but during ordinary eruptions a deposit of some inches in depth is spread over vast areas, supplying a "top dressing" that our farmers would envy, and which would put an end to the artificial fertilizer trade if we were within reach of such volcanic beneficence. By an analysis made by L. Ricciardi of ashes ejected from Vesuvius on February 25th, 1882, he found in them four and one-third per cent of phosphate of lime and more than five and one-half per cent of potash, and the ash evolved a sensible quantity of ammonia when treated with caustic potash. These and other constituents indicate a valuable fertilizer.

Decomposition of Feldspar by Humus.

A Russian named Meschtschersky has been experimenting upon the decomposition of common feldspar by humus both in the laboratory and in the garden. Finely ground orthoclase was sealed up in a glass tube with humus and water and heated for nine or twelve hours daily to 115 degrees C. (239 degrees F.), for one or two months; he then filtered the contents of the tube and examined both residue and filtrate. Another experiment was conducted under ordinary conditions, the orthoclase and humus being placed in a tin box with double bottom and buried in a garden for six months.

In both cases the orthoclase was decomposed. The composition of the feldspar employed was as follows: Silica, 62.02; alumina and oxide of iron, 23.93; lime, 0.25; potash, 7.21; soda, 4.39.

The humus was obtained by the action of sulphuric acid upon racemic acid. When washed and dried at 120 degrees C. it consisted of 57.17 per cent carbon, 4.59 hydrogen, 37.96 oxygen, and 0.28 ash.

He draws the following conclusions from his experiments: 1. Orthoclase is decomposed by humus in the presence of water, giving up its constituents to the humus and taking up water. The separation of silica, alumina and soda are the easiest, that of potash the hardest. Hence there is an essential difference between this decomposition of orthoclase and weathering. 2. The humus is partially decomposed into carbonic acid and water, and partially converted into soluble and insoluble mineral compounds of humus. 3. The decomposition is directly proportional to the time and temperature.

SERPENT VENOM.—The destruction of human life by the bites of poisonous serpents is so great in many countries, that it becomes really an important problem to ascertain the amount of damage, and to seek the remedy. Dr. Robert Fletcher has brought together much information, in a paper read before the Washington Philosophical Society in May last. Sir Joseph Payrer states the average mortality from serpent bites in India to be fully 20,000 annually. In 1869 the returns were obtained through official sources, from a large part of India, with unusual care and accuracy. In a population of nearly 121,000,000, representing an area of less than half the peninsula of Hindustan, the deaths were 11,416, or nearly one in 10,000. Of these deaths, there were caused by the cobra, 2,690; krait (Bungarus ceruleus) 359; other snakes, 839; unknown snakes, 6,922; no details, 606; total of 11,416. In 1880, 212,776 poisonous snakes were killed and paid for in British India; and in 1881, 254,968. Even in Europe and in this country, the number of accidents from snake-bite is very large. In one department of France, La Haute-Marne, the government paid, in six years, for the destruction of 17,415 vipers.

PLANT DEVELOPMENT IN HIGH LATITUDES.—A Norwegian plant geographer, Professor Schubeler, called attention a short time ago to the remarkable fact that most plants in high latitudes produce much larger and heavier seeds than in warmer regions near the equator—an effect which he ascribes to a prolonged influence of sunlight during the long summer days of the high latitudes. In some cases the dwarf beans taken from Christiania to Drontheim, less than four degrees further north—gained more than sixty per cent in weight, and thyme from Lyons, when planted in Drontheim, showed a gain of seventy-one per cent. The leaves also of most plants are larger and more deeply colored in higher latitudes, as was first noticed by Griesbach and Martins. The same is true of flowers, and many which are white in southern climates become violet in the north.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RICH STRIKE.—*Dispatch*, Dec. 22: A body of very rich rock was struck last Tuesday in the St. Julien mine, on Murphy's Ridge, owned by Moore, Conlon, Price, Caminetti & Co. The full extent of the body is not yet known, but the specimens of rock taken out show a large amount of sulphuric acid and a considerable quantity of free gold. The mine is located near the celebrated Nevills mine, and there is every indication that the strike will prove to be a very valuable one. The proprietors feel highly elated over their prospects.

ST. JULIEN.—The *Ledger* of same date says of the strike and of the mine: This quartz mine is situated near Middle Bar, on the main mineral belt. It adjoins the Mammoth claim on the south. It has been bonded to Messrs. George Moore, A. Caminetti, J. R. Price and Thos. Conlon. The work done upon it lately consists in running a tunnel into the side hill in a northerly direction. The tunnel has reached a distance of 115 ft. and about 40 ft. from the surface. Last Tuesday morning quartz was struck on the footwall. How extensive the strike remains to be seen. The find is important on account of its proximity to the famous Mammoth mine. The strike is 400 feet from the boundary line of the Mammoth ground. The big tunnel will explore the Julien ground at a depth of 800 ft. from the surface. Since the above was written further prospecting proves that a pocket has been stumbled upon. The owners brought up Thursday evening three sacks of ore, composed mainly of arsenical sulphurets, iron and gold, mixed with quartz. The ore is very heavy, a small sack being as much as a man can lift. It is of a black color, and when burnt shows considerable gold. Altogether it is of the same general character as that met with in the famous Mammoth pocket, except, perhaps, that it does not carry so large a percentage of gold. As far as explored, the ore body is from six inches to a foot in width. It widens as it is followed deeper. The discovery has created quite a stir in the vicinity.

LINCOLN.—S. D. R. Stewart, who has leased this property, proposes to start work immediately. The intention is to clean out and sink an old shaft east of the present shaft, and near the Iowa line. The pocket lately taken from the Iowa encourages hope.

NOTES.—It is reported that the Wildman mine, Sutter Creek, has changed hands, the purchasers being San Francisco capitalists. Some fine specimens of sulphurets were brought to Jackson Tuesday, by a Mexican, the place of discovery being in the vicinity of Clinton. The big tunnel at Middle Bar is now in a distance of 300 ft. The best prospect for a big mine in Hunt's gulch is reported to be at Doyle's claim. It continues to develop splendidly.

THE STRIKE.—*Sentinel*, Dec. 19: The full extent of the strike has not been ascertained, but in expectation the owners are trembling with excitement as visions of becoming Mackays and Floods float before their disordered sight.

Frank Guerra, who is working on the Morgan claim in Hunt's gulch, is reported to have made a rich strike. The Bartlett brothers are waiting for time to run their gravel mine at Slabtown. The Tripp and Littlefield mine near the Big Bar bridge has again been started up, and is working six men.

Calaveras.

MAMMOTH EXTENSIONS.—*Chronicle*, Dec. 29: In republishing an account of the "find" recently made in the St. Julien, which mine is situated only 3 miles from this town, but on the Amador side of the Mokelumne river, it is well enough for us to state that several well developed ledges have been discovered and located on the Calaveras side of the river of late, all of which seem to be extensions of the ledge of the celebrated Mammoth mine. San Francisco capital has taken hold of some of the properties on this side, and we feel safe in saying that Calaveras, as well as Amador, will soon have a boom in quartz.

CARSON HILL.—The new mill being erected by Wm. Irvine, at Carson Hill, is about completed and will soon be crushing quartz. The Melones mill—40 stamps—is running day and night. There is a hotel, two saloons and a great number of dwelling houses at Carson Hill at the present time.

Mariposa.

THE MOTHER LODE.—*Mariposa Gazette*, Dec. 29: The value of the great mother lode which runs through Mariposa, Tuolumne, Calaveras, Amador and other counties, is just beginning to be realized. Although the mother lode has been profitably mined in Amador county for many years, mining on it in Tuolumne and Calaveras has, until recently, been of an unsuccessful character. Of late years mining men have begun to understand what difficulties are to be encountered, and what is necessary to overcome them. As a consequence, the importance of the vast deposits of low grade quartz in the mother lode is now forcing itself upon the notice of the mining public. At Angels Camp, in Calaveras county, the mother lode is mined and milled at an expense of \$1 per ton, and one Supt. says he is going to reduce the expense to sixty cents per ton. As the lode is over 100 ft wide, and yields about \$4 to the ton, it is easy to see what a bonanza it is. In this county there are many places where the great lead could be successfully worked if capital, experience and a thorough knowledge could be brought to bear.

Mono.

MAY LUNDY.—*Honor Index*, Dec. 29: The May Lundy is being worked with the usual force, and the tramway has not yet been obstructed by snow, though on account of the drifting of the snow in the upper canyon teams have not been hauling ore this week. The mill is kept going steadily day and night, and the bullion shipments are regular.

NEPTUNE NO. 2.—J. R. Crane has completed arrangements to increase the working force on Neptune No. 2, Jordan district, as soon as the holidays are over. The surface cut last summer revealed a large ledge and some very rich ore.

CLIFTON.—The Clifton mine, on the north slope of Mount Scowden, just above Lundy, is rapidly coming to the front. About half way from the entrance

to the header of the old tunnel an incline winze is being sunk, and, from about three ft. in width at the tunnel floor, the fissure has expanded to six ft. seven inches in sinking ten ft. Vein matter fills the entire space between the walls, with three strata, each fully one ft. in thickness, of very rich ore.

Placer.

FOREST HILL.—*Placer Herald*, Dec. 29: The Mayflower M. Co. started up their new 10 stamp mill last Saturday. It is working splendidly. The Breece & Wheeler diggings are taking out some fine gravel, some of it yielding as high as \$10 to the pan, but the gravel is getting lower than the tunnel thus making it more difficult to take out. The Washington Co. is getting its buildings ready for the new hoisting and pumping machinery which will soon be up. Taking it altogether the mining outlook on the divide is very favorable.

Plumas.

HALSTED MINE.—*Greenview Bulletin*, Dec. 26: On last Friday the face of the tunnel in the Halsted mine was within ten ft. of the ledge, according to survey. This ledge proves to be more extensive the more it is examined. From Rich gulch it can be traced entirely through the mountain ridge to the opposite side, on North Fork, a distance of five miles. In many places it crops out several ft. above the ground, and in other places it is covered by lava or other matter, but over this whole distance wherever sought for it can be found, and in all places has the same general character. For some time past Joe Halsted has been running an arastra on the ore at Rich gulch; last week he made a clean up after a run of three weeks, and found that the rock crushed in that time had averaged \$32.50 per ton. Should the ledge hold out at even half this value it would be the greatest mine in the State, when the supply of ore and facilities for working it are considered.

DEADWOOD.—Bob Bone has located a claim on the Rich gulch ledge at Deadwood, on the North Fork side of the ridge, and is at work there now.

San Bernardino.

ORO GRANDE.—*Los Angeles Herald*, Dec. 29: The Oro Grande Mining Co. has declared a monthly dividend of \$6,000, making a return to its stockholders of \$1,000 since the 1st of March last. The company has purchased the ten-stamp mill of the Oriental Company, of Calico, and will add five more stamps. The improvements will be completed in about forty days. The Oriental mill is but six miles from the mine, which will save a transportation of thirty miles on the ore. The leading stockholders in the Oro Grande Co. have also purchased a controlling interest in the Burning Moscow, which adjoins their great King mine, and will set to work to open it out in good style. This mine is now in able hands and will undoubtedly give a good account of itself. Secretary Johnson, of this city, will superintend the reduction of ore in the Oriental mill. The Oro Grande mill, with its fine water power, will probably be run on custom ore, unless the company conclude to develop the mines that lie near the mill.

MOHAVE DESERT.—The *Los Angeles Republican* has the following: Messrs. James Noel and George Turner, well known citizens of Los Angeles, have returned from a visit to a new mining camp in San Bernardino county. They bring with them some very rich specimens of ore and chloride of silver. The mines are situated upon the edge of the Mohave desert, about forty miles south of Calico, and 120 miles from Los Angeles. Mr. Noel, who is the president of a company incorporated for the purpose of working these mines, exhibited several specimens of ore from the Soledad and the Sanchez mines. That from the Sanchez vein was from a depth of more than one hundred feet, and is fully 50 per cent silver. The vein from which this specimen was brought is narrow, but is flanked by large quantities of ore of a lower grade, the richest ore running through it in streaks. The Soledad and Sanchez mines are being worked with imperfect facilities, but a large amount of ore is being accumulated in anticipation of the coming of a ten-stamp mill which has been ordered from the East.

Shasta.

EAST FORK.—*Democrat*, Dec. 26: Levi Day was in town last Monday and reported everything lovely at the East Fork quartz mine. The arastra is all ready to start up as soon as they have water. They have about 20 tons of rich rock at the arastra and a lot on the dump.

JUNCTION CITY.—The continued dry weather has demoralized the news department of this place, as there is nothing transpiring worthy of note. When we have plenty of rain and the miners get well at work, then we will have plenty of news. Notwithstanding the extremely dull times every one is cheerful and hopeful. For the last eight years we have not had water to mine with before the latter part of January.

"OLD DIGGINGS."—The *Redding Independent* of Dec. 28th credits the following to the Red Bluff *Tocsin*: G. W. Fleming has placed on our table samples of the quartz taken from his newly discovered gold quartz mine (the Texas) located in Old Diggings, Shasta county, Cal. The quartz when burned shows free gold to the naked eye. It assays \$75 to \$100 per ton. Mr. Fleming tells us that he has crushed about twelve tons of select ore which averaged about \$50. He has gone down 12 ft. The average width of the ledge is 3 ft, standing in solid casing. Much of the rock has free gold in it.

Sierra.

COLUMBO.—*Sierra Tribune*, Dec. 27: Last Thursday the whistle at the Columbo mill sent forth its first notes, telling the people of Sierra City and of the whole county that another great enterprise had sprung into life. The machinery ran like clockwork. The double-track tramway was also found to work satisfactorily upon being tested. It was expected to begin crushing ore Monday. The vast amount of work that has been accomplished in and around the mine during the past four or five months, and the manner in which it is done, proves conclusively that Supt. Deidesheimer is the right man in the right place.

RUBY MINE.—Everything was in readiness last week to put on a crew of 70 men as soon as water should come. H. Pichoir and H. C. Miller, stockholders in the mine, were up from San Francisco last week. They expressed themselves highly pleased with the present promise of the mine. Mr. Pichoir carried away 40½ ounces of bullion, the yield of 320 carloads of gravel taken out of the main tunnel. The

Co. have recently purchased from James McNaughton, of Forest City, and George Paterson, of Oakland, the City of Six mining claims and water right. The price paid was \$1,500. This gives the Ruby Co. exclusive rights to the water of Rook creek and possession of quite a large tract of mining ground.

SIERRA BUTTES.—No. 9 tunnel, at the Sierra Buttes mine, is being pushed ahead at the rate of 30 ft. per week. The rock is getting softer, requiring the tunnel to be closely timbered. The first ore body will be tapped in the neighborhood of 1,000 ft. further. A whistle has lately been added to the works at the lower tunnel. It is expected to have the new mill in operation next spring.

FOUR HILLS.—Eleven men are employed at the Four Hills mine at present. These are principally engaged in doing work. The mine is in a fine condition and a large body of rich ore is in sight. The mill will start up when water begins to flow. George Reynolds, Jr., was down from the mine this week.

Siskiyou.

CALLAHAN ITEMS.—*Yreka Union*, Dec. 20: The only claim working at present that we know of is Mitchell & Co. They are in good ground and have done well this season; the drier the season the better for them. There is some quartz excitement. Bob Small showed the writer a nice piece of quartz with an abundance of free gold in sight that he says assays \$2,000 to the ton and that they have several tons out that will go \$65 to the ton, and a ledge traced 1400 ft. on the surface, rich all the way. Chas. Hall returned lately from the Cariboo mine on south fork of Salmon, where he lately finished the erection of a quartz mill for Bennett, Abrams & Shultz. Their quartz prospects well.

IRON MOUNTAIN.—We are informed that a party of capitalists has formed an association for the purpose of working the ores of Iron Mountain, between Pitt and McCloud rivers. The company intend to erect large smelting works and manufacture steel rails. The smelting works will be erected at the junction of Pitt and McCloud rivers, from which place to the mine, a distance of 8 miles, they will build a narrow gauge railroad to convey the ore from the mine to the smelter. The erection of the smelting works and the building of the narrow gauge road will occasion the outlay of a large sum of money, and the company expects to have 1,000 men employed by the 1st of March.

Trinity.

IGO.—*Cor. Journal*, Dec. 29: The Hayward or Hardscrabble hydraulic mine has been fitted up in good shape and will commence yielding treasure as soon as the required amount of rain comes, which will be about the holidays or we are no prophet. Mr. J. W. George and the Hoskins Bros. have recently made a clean up of \$700 from 13 tons of ore from the Rattlesnake mine, Bullyhoop district.

NEW RIVER.—*Cor. Journal*, Dec. 29: The storm of the early part of October created a general stampede of quartz miners from here. Some have gone to San Francisco and others to Humboldt county to pass the winter. They will resume work in the spring. We have been informed that there will be one, and perhaps two, 5 stamp mills put up here next summer. Ladd, Clifford & Co. were the last to decamp. They carried with them 16 lbs. of amalgam, weight on the grocery scales at the new river store, from seven days' run of their arastra on ore from the Mountain Boomer ledge. The placer miners are waiting with their usual patience for the winter rains to set in.

Tuolumne.

RICH ROCK IN THE PATTERSON.—*Sonora Democrat*, Dec. 29: The Patterson mine at Tuttle town is developing wonderfully of late. In the bottom of the incline, at a depth of 650 ft, the ledge is more than 18 ft wide. The rock is richer than any ever struck in the mine before. Chunks as large as a water bucket come up fairly glistening with fine gold, while here and there through the rock are heavy pieces of coarse free gold. A good deal of the rock is impregnated with lead sulphurets, which are very rich. At no time in its history has the mine made such a splendid showing as it does to-day.

RAWHIDE.—Operations have been resumed in the O. K. mine at Rawhide under the superintendency of John Dart. Some very rich rock was taken from the O. K. in the past, and we may expect favorable developments in the future.

NOTES.—William G. Long has obtained the entire control of the Willietta mine, at Jacksonville, having purchased Thomas Whitto's interest. It is Mr. Long's intention to commence the work of development right away. A 20 stamp mill is to be erected on the mine as soon as practicable. M. Foot and B. Hunter are running a tunnel on the vein in the Blackhawk mine, at Groveland, and are taking out some good rock. They think the prospects excellent. George A. Koch, of the Riverside mine, has bonded ten mining properties on the Stanislaus river, near the Riverside, from Col. Caleb Dorsey, of Oakdale, and others for \$375,000. Frank Gross is in high feather over the prospects of the Washington mine near Groveland, of which he is part owner with Steve Thomas and others. The shaft is down 40 ft, with a large ledge of fine looking quartz in the bottom.

HUNTINGTON QUARTZ MILL.—In last week's *Press* appeared an item clipped from the *Sonora Democrat* which gave the inference that the shutting down of the Garibaldi mine was due to the non-success of the mill. The following letters show that this is incorrect and explain themselves:

Mr. F. A. Huntington, San Francisco—Dear Sir:—In reply to your inquiry concerning the alleged failure of the new Huntington crusher (*Sonora Democrat*, Dec. 15) used in the Garibaldi mine, I take pleasure in saying that the mill gave entire satisfaction. The mine not proving successful caused the works to be shut down, but it was in no sense the fault of the mill.

E. J. PARSONS, Supt.
GARIBALDI MINE,
Calaveras county, Dec. 17, 1883.

F. A. Huntington—Dear Sir:—In answer to your inquiry concerning the working of the five ft. "centrifugal pan mill" bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect; and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

O. B. SMITH, Manager.

NEVADA.

Washoe District.

OPHIR.—*Enterprise*, Dec. 29: Are still extracting some ore from 150 level. Good progress is being made in the winze that is being sunk below the 150. At a proper depth this winze will be connected with the main shaft, which has been put in good repair down to the 500 level, when explorations for ore can be economically made.

YELLOW JACKET.—A limited amount of ore is being extracted. A full force of miners cannot be put to work until there is a full head of water in the Carson river, or until the machinery is connected with the steam power recently placed in the Brunswick mill.

SIERRA NEVADA.—The raise from the main north drift on the 2900 level is going up at the rate of about 16 ft per week. The ground is dry and favorable. On the 3100 level a northeast drift has been started, and is now out about 15 ft.

HALE AND NORCROSS.—The work of pumping out the winze below the 2700 level is about completed. It is nearly all dead water—water that flowed in at the time of the accident to the Cornish pump at the Combination shaft.

COMBINATION SHAFT.—The work of setting up the new hydraulic pump at the 2600 level is progressing favorably. When the pump has been put into successful operation sinking the main shaft to the 3000 level will be resumed.

GOULD AND CURRY.—The joint Best and Belcher winze below the 2500 level is going down at the usual rate of speed. The ground at the bottom is somewhat soft and wet, but, on the whole is not unfavorable.

UNION CON.—Good headway is being made in the main south drift on the 3100 level. It continues in vein porphyry. It will connect with the main north drift in about two months.

CROWN POINT.—Some ore is being extracted, but a full force of miners cannot be employed, owing to the limited capacity of the mills on the Carson river in the present low stage of water.

UTAH.—The north lateral drift on the 1750 level is being pushed along quite rapidly. It is now over 100 ft. Thus far the formation is favorable.

ALTA.—The 2150 level—the lowest in the mine—is drained, and is being put in repair preparatory to a resumption of active prospecting operations.

MEXICAN.—Are making good progress in the work of timbering up the main north drift on the 3100 level and putting in drain boxes.

BEST AND BELCHER.—Good headway is making in the work of sinking the joint Gould and Curry winze below the 2500 level.

UNION SHAFT.—Are still engaged in easing up behind the timbers and in making needed repairs to the 2300 station.

IMPERIAL.—The main west drift is now within a short distance of the upper levels, which it is intended to explore for ore.

CALIFORNIA.—Fair progress is making in the joint Con. Virginia winze now being sunk below the 2700 level.

CON. VIRGINIA.—The usual progress is being made in sinking the joint California below the 2700 level.

ANDES.—Prospecting continues at the usual points, and some low grade ore is being found.

SCORPION.—The usual progress is being made in the main west drift on the 500 level.

OVERMAN.—A small amount of ore is being taken out of the old upper levels.

BELCHER.—Some ore is still being extracted from the old upper levels.

Belmont District.

BELMONT MINE.—*Courier*, Dec. 22: They are still encountering rich ore in the south portion of the Belmont mine. The prospects in the 200 south level are improving as the work of development advances. All is looking well in the other portion of the mine. Following is the official report for the week: The three south stopes on 200 level are all looking well; ledge carrying from fifteen to three ft. of good ore. Ledge in north stope, same level shows six ft wide and widening rapidly. Stopes in South Tunnel yielding the usual amount of high grade ore.

NOTES.—C. B. Streiberger informs us that the new discovery made in the 2 G mine at Tybo is proving a valuable one. When he left that town the ledge measured thirteen ft in width, and the ore extracted from it is of excellent quality. The mill is running nicely, producing excellent bullion. Green Aldrich has started the Emerson mill and leaching works. He is now leaching ore from the 77 mine. Messrs. Bartell, Hall and Colligan are encountering some rich ore in their mine, north of town.

Bernice District.

LATEST.—*Silver State*, Dec. 22: W. A. Van Reed who arrived at Reno a few days ago from Bernice district tells the *Journal* the following: It is situated in the southeastern part of Humboldt county, and about half way between Lovelocks and Austin. About fifty miners have been at work in the district for the past two years, and have developed a number of good mines—the Golden Crown, Wild Goose and White & Gilbert being among the best. The owners of the White & Gilbert have been shipping ore to Salt Lake for the past year, realizing \$206 per ton. G. W. Bothwell built a small custom mill in the district last spring, and found no trouble in keeping it at work on good ore all summer, and it was only shut down a few days ago in consequence of a scarcity of water. Work in the mines will be continued all winter in order to have a good supply of ore on hand when the spring opens.

Candelaria District.

COLUMBUS CON.—*True Fissure*, Dec. 29: During the past week good work was done in all the important points in the mine. The third level station was completed and the work of running a drift from that point towards the location of the Bonanza winze is now under way. The drift from the location of the Bonanza winze has attained a length of 65 ft; the face is now in good working ground which gives good assays. Since the last report the south cross-cut from the 150 level was extended 15 ft, making a total length of 45 ft.

MOUNT DIABLO.—The east drift from lower winze No. 2 is in 82 ft and shows a few inches of \$604 quartz.

Winze No. 5 is down 30 ft and shows a small amount of ore. The south crosscut from the west drift on third level is in 40 ft. A bullion shipment amounting to \$8,586.70 was made on the 24th instant.

THE FIRE.—The fire of Dec. 15th at Candelaria destroyed sixteen buildings. Nearly all the south side of Main street is in ruins, except the Esmeralda County Bank, which is fire proof. The losses foot up to nearly \$100,000; insurance \$30,000. R. K. Gamble & Co. and H. G. Smith are the heaviest losers. A scarcity of water was the cause of the fire spreading. This disaster, following on the closing down of the Northern Belle mine, has cast a gloom over the town.

Esmeralda District

MOUNT CORY.—Hawthorne Herald, Dec. 22: "The result of this outlay of time, labor and coin, warranted the Mount Cory Co. to construct reduction works on a gigantic scale at a cost of hundreds of thousands of dollars which will be in operation inside of two months. The successful working of their ores to a high percentage of the assays, same having been tested at the Geddies Bertu and works, Eureka, leaves no fears for a failure. The pay-roll at the Mount Cory reduction works last pay day footed up nearly \$32,000.

LURING.—Mr. J. R. Benton has a force of men working upon his mines. He expects to make another heavy shipment soon. Messrs. Baecigalopi & Sheller have a carload of very rich ore here, awaiting shipment. It is from the Stone Cabin vein and will go for more than 30 per cent. Mr. Murray and party are taking out considerable first-class ore at the Dumbarton Springs. They make a shipment this week. The hills are alive with assessment workers and prospectors, and people throughout the entire range feel encouraged.

Eureka District.

ENTERPRISE.—Sentinel, Dec. 27: The Enterprise mine, Foreman Williams tells us, is looking better as developments advance. The ore body is a ledge varying from 4 to 6 ft in width, with one wall exposed, the upper, the hanging wall, being removed by a back ledge recently discovered. The ore being taken out is galena and reddish carbonates, some of which is high grade. Mr. Williams says the furnace is working to a charm, and that the average value of the bullion reduced is \$150 per ton. The total expense involved is something less than \$120 per ton, so that there is a clear margin of \$30 profit per ton left. There are 23 men at work on day's pay, and more men are to be put on at once. There are about 40 men altogether in the camp employed by the Enterprise Company.

BALD MOUNTAIN.—Luther Clarke and his partners have a claim in Bald Mountain district that bids fair to make them all rich. In the claim referred to they are down 18 ft in overall the way. The width of the deposit is not yet known, as the find is of recent date. The ore is soft and reddish, and a number of specimens taken from the top of the workings to the bottom assay from \$123 to \$396. Work has been going on right along, but nothing has been heard from the mine in the last week.

Oseola District.

VERDI.—Cor. Southern Utah Times, Dec. 18: The Verdi mine, owned by D. Akey & Co. is bonded to a San Francisco company. The mine is situated about three miles south of the town of Oseola, and is one of the richest mines in the district. The ledge is stripped and opened with cuts and drifts for a distance of 400 ft, showing very rich free gold quartz. They also have a shaft sunk 60 ft, showing the same character of ore. They have about 20 tons of first-class ore sacked that will go up in the hundreds. They have also a large amount of second-class ore on their several dumps ready for milling. This mine is well situated for working advantageously. The ledge can be cut to a depth of 500 ft by a tunnel not to exceed 650 ft in length. The owners of this property also have a water right that affords sufficient water for 20 to 40 stamps.

THE OSEOLA MINE.—The Ward Reflex says: While in Oseola, A. B. Treece and Samuel Liddle went through the Oseola mill, which had been running some six or eight days at the time of their visit. They report that 35 tons of ore per day have been put through the mill since it started, and there is a good showing of amalgam, and that Mr. Turner, a Bodie millman, who is in charge, says that the result to date comes up to expectations. Ore is at present being put through the mill from all portions of the mine, which has been developed all along the line.

Revielle District.

MANHATTAN.—Grass Valley Union, Dec. 30: Although the Manhattan mines have been working continuously for 20 years, and have produced \$20,000,000, they are still quite shallow, the deepest not being over 1200 ft. The smallness of the ledges cause this. The ore is very rebellious and it is very expensive to work. It costs \$35 per ton to reduce the ores taken from their best mines, and these are the easiest worked of any found in the canyon of the Toiyabe range. The hills are full of ledges which will assay \$50 or \$60, but it will not pay to work them, for by the time they pay for mining, milling and the twenty per cent discount on silver, there will be nothing left. What is wanted is a process that will work this ore at \$4 or \$5 per ton. The discovery of such a process could make money faster than a Bonanza King by charging a small royalty on each ton worked. The Manhattan mines give good promise of permanency, for at the bottom of the deepest mine they have found as rich rock and as fine a looking ledge as they have ever had. This is very encouraging to the people there whose only hope is the Manhattan. If it fails there is nothing left. There are many Grass Valleyans there, as there are in every camp on the coast. Austin's altitude is 6,500 ft above the sea level.

ARIZONA.

UNITED VERDE CO.—Prescott Courier, Dec. 21: Mr. Thomas, the superintendent, commenced smelting some time in August last, and will, by January 1, 1884, have smelted 5,000 tons of ore and made 1,000 tons of copper bullion and copper cake, worth in the neighborhood of \$300,000. The smelter runs out every 24 hours from 10 to 12 tons of copper. Mr. Thomas once tried to see how much he could run out in 24 hours, and succeeded in getting 15 tons, less one pig of 500 lbs. This was wonderful for a 30-ton furnace. It is now yielding about \$3,000 a day, more than one-half of which is clear gain, over

and above expenses of every kind. Seven hundred mules and ever so many wagons are employed in hauling ore, coke, etc., and the number of men in the company's employ is about 120.

CONTENTION.—Tombstone Epitaph, Dec. 23: The pumps are running with the utmost regularity, keeping up a speed of three strokes to the minute, which could be increased if necessary more than double. The main three compartment shaft is being sunk as rapidly as possible. While sinking is pursued work in the stopes and levels is by no means neglected, and the usual amount of ore is extracted. The ledge in the bottom of the shaft is holding its own splendidly.

MAMMOTH.—From the 220 level a winze is being sunk. The same tapped a few days since a large ore body contained in a cross ledge. It has been traced from the surface, but only lately has developed into a large body, promising to equal if not to surpass the main ledge running north and south. Most work done on this mine has been development work. Since last March, at which time the present owners purchased this mine, the bullion production has averaged \$30,000 per month.

SILVER KING.—Pinal Drill, Dec. 22: The King Co. has paid in dividends \$1,300,000 and the stock stands at 57 1/2. Capital stock 100,000 shares. Now there are 100 men employed in the mine; they have just finished their new spacious changehouse and also a beautiful, cozy little mess house for the officers.

THE QUIJOTOS.—The Virginia Enterprise of the 28th of Dec. quotes from the Florence Enterprise as follows: The rush toward the Quijotos company has commenced. A prospecting party from Pinal and Silver King, consisting of John McCoy, Pat Donahue, Buck M. Dowell, W. Harris, Joe Baker, D. L. Beesley and Mr. Lewis, passed through here Wednesday en route to the new El Dorado. They had a 4-mule team, a wall tent 14x16, a complete outfit of mining tools and camp utensils, and enough provisions to last them two months. Several other small parties from other sections and bound for the same destination passed through here this week.

COLORADO.

THE WHITLOW LODGE.—Idaho Springs News, Dec. 21: The vein matter, already tested, is five ft wide, a cord of which run over the tables of the Golden Leaf mill by Dr. Barber, gave \$60 dollars. Even at the low figure of \$60 per cord, there is an immense fortune to be made by the owners of this property working it with a small stamp mill of their own or two batteries. On such a mill two cords of mill dirt could be crushed every twenty-four hours, making \$120 per day. The mill dirt could be mined by eight men, working day and night shifts on a five ft vein like the Whitlow.

MENDOTA.—Georgetown Courier, Dec. 22: Shay & Co., during the past week shipped two carloads (28 tons) of Mendota ore to Messrs. Mathews & Webb, from which returns have not yet been received. Mr. Shay tells us, however, that it is the best ore ever extracted from the mine. It was taken from two small stopes, one in the east and one in the west drift, about 70 ft below surface.

NEVADAVILLE.—Register-Call, Dec. 21: The Hubert mine is now giving a daily output of ore—mill or stamp dirt—which gives employment to 15 stamps. In the 900 level workings of the Kansas mine, worked under the management of the Denver Mining Co., the ore treated under the stamps has an average of nearly six ounces gold per cord.

COLUMBIAN MOUNTAIN.—Georgetown Courier, Dec. 20: On the Joe Reynolds, Farris & Co., lessees, have commenced sinking from the lower workings of No. 1 500 ft from the surface. They have 14 inches of solid ore. In sinking the first four and a half ft, 110 sacks of ore were taken out. Twenty-nine men are at work on the properties, all of whom are in good ore excepting one set of lessees, who are developing for a known body of good ore. The Reynolds properties, without doubt, have more ore in sight than any other property in the county.

LITTLE EMMA.—A mill-run of ore last week returned for 1st class, 1195 ounces silver per ton, and 2d class, 300 ounces. The Little Emma is one of the group of mines in its vicinity that produces the highest average value of ore per ton of any in Clear Creek county.

IDAHO.

MINERAL DISTRICT.—World, Dec. 21: The Daniel Boone mine at Mineral has been bonded for six months for \$20,000. The tunnel will be run in 200 ft to tap the ore body 400 ft deep. Times are quite lively at Mineral. Peck and Jones, on the Kit Carson, are getting the same kind of ore as the Black Maria, with the tunnel in about 40 ft. John Morris, on the True Blue, is getting good-looking rock, in 30 ft. There will be a number of large sales made in the camp within 30 days.

QUARTZBURG.—A cross-cut is being run from the 400 level of the Gold Hill mine, Quartzburg, for the Pioneer ledge. The cross-cut is now, it is thought, within 50 or 100 ft of the Pioneer. These two ledges are 140 ft apart at the surface, and according to an estimate based on the angles of the dips of the veins, the Pioneer will be reached with cross-cut from 400 level of Gold Hill, between 400 and 500 ft in length. The former has not been worked below the depth of 30 ft. It paid well at the surface—turned out \$160,000. It is owned by the Gold Hill Co.

ELKHORN.—World, Dec. 18: Hugh Turner is working eight men in the Elkhorn mine. They are prospecting for a pay chute some distance west of the old works. Hugh says they will probably not take out any rock before spring. Will put in the winter prospecting.

MINNIE MOORE.—A winze has been sunk from the 150 level of the Minnie Moore to a depth of 30 ft. At the bottom of it a 6 ft body of galena has been encountered. Up to November 1st work had been done entirely above this level. The mine is shipping now, and will continue to do so all winter, 12 tons of ore daily.

DEER CREEK.—Wood River Times, Dec. 19: About 150 men are at work on Deer creek this winter at the several mines, and a great deal of development work will be done. Many claims are being worked that would have closed down a month

ago but for the continued fine weather which has given them a chance to put up winter quarters. The Montann, Davitt, Keystone, Snow-Fly, Mount View, Emery, We-met-by-chance, Sunday Night, and several others, will work a force all winter. The Davitt Co. has the lumber on the ground for the hoisting works, and the buildings will soon be finished. The output of ore still continues large at the Narrow Gauges.

VIENNA MINES.—Ketchum Keystone, Dec. 19: Tom Tague has three teams at work hauling from 35 to 47 tons of ore per day from the Vienna and Mountain King mines to the mill. Four hundred tons are now in the ore house and 1,300 will be there by March 1st. Seventy-five men are employed in the Vienna mine, thirty-five in the Mountain King, and thirty-five at the mill. A tunnel has been started 400 ft below the old works of the Vienna to tap the vein 400 or 500 below the surface. Six men are at work running a tunnel to tap the Lion and develop it. The Vienna mill is gaining a bar a day, and the Co. is storing the odd ones, which will be shipped on a special. Five extra ones are now on hand. From 23 to 26 tons of ore is milled per day. It is of an extra high grade.

BULLION MINES.—World, Dec. 22: Fifteen men have been discharged from the Idahoan mine, leaving the force at fourteen. The night shift has been dispensed with, and the concentrators stopped. The mine is looking fine, and on the 200 level they have twenty inches of high-grade ore. Up to the time of cutting down the force, from 50 to 60 tons of ore were extracted daily. Twenty-six men are at work in the Bullion. The Mayflower is working 60 men, but will discharge some in a few days. Work on the Jay Gould has been entirely suspended.

CEUR D'ALENE.—Cor. of Eureka Sentinel, Dec. 27: As I am an old reader of your valuable paper I will give you my opinion of this camp. To begin with, it is the richest thing I ever saw. I have taken in all the mining camps on the coast. There are only three or four claims open as yet. In what is called the Willow claim, they clean up from \$100 to \$175 per day with eight men at work. There are two miners in the gang; the rest are hay pitchers. The other claims make about \$5 or \$10 per day. Now the bed-rock is frozen so hard that they don't get one-half of the gold. It beats anything I ever saw. All the hills around will run from 20 cents up, to the pan. Five hundred ft above the creek the best claims, so far, are on Pritchard creek. It is located for twenty miles. They are hunting quartz on snowshoes now. Every day turns up something new. A lot of Leadville mining men came in lately. After looking the mines over they laid out a town for over one mile in length. They say there will be over 20,000 people here by June. Town lots have jumped from \$25 to \$500 in two weeks. I don't think there are over 500 men, all told, in the district. We had a heavy snowstorm, which drove out all the men that did not have supplies to go on. Over 100 houses and cabins went up in the last two weeks, and the axes and whipsaws are ringing in every direction. Freight is \$20 per 100 pounds. For 40 miles the river is full of boats frozen in with goods—mostly whiskey.

The World, of 18th, credits the following to the Nez Perce News: T. M. Davis, of Farmington, who recently came from the Ceur d'Alene mines, says on his way out he met 75 Montana miners going in, and that 500 miners from Montana are expected to winter in Eagle City. The total population of the mines during the winter will be over 700 men. Very few persons are selling their claims, although opportunities to do so are not lacking. Although large quantities of provisions are being packed into the mines, Mr. Davis thinks food will be short before spring. All of the packing is being done by Indians who receive seven cents a pound for all the freight they carry over the trail. One Indian company has over 100 ponies engaged in packing. Oats are worth ten cents per pound on the Mullen road.

"THE WIDOW'S CLAIM."—Inter-Mountain, Dec. 23: "The Widow's Claim, so called, was located by the discoverer of the diggings for the woman who staked Pritchard in his explorations. The claim was jumped by a party of men, and out of it has come a good part of the gold thus far washed from the gulch. The widow (whose name is Mrs. Edgington) proposes next season to make a fight for the recovery of the ground. She hails from Virginia City, Nevada."

LATEST.—Virginia City Enterprise, Dec. 23: John McKay, just come in to Butte, Montana, from Ceur d'Alene, reports the trail broken into the mines from Rathdrum, and that four pack trains have gone in there since the 1st instant. About 75 men will winter there. Mr. McKay is very much elated over the gold and silver quartz discoveries, but echoes the suggestions of others that no one should attempt to go to the mines before spring. He also says that the miners will not allow a Chinaman in the district.

MONTANA.

FISH CREEK.—Helena Independent, Dec. 20: A few days ago we made mention of the reported discovery of rich placer diggings having been found on Fish creek, about 20 miles from Butte. The report has since been confirmed by J. W. Shields, of Butte. The gulch is eight or ten miles in length, and has nearly all been taken up in 20-acre claims. It is four or five miles below Highland gulch, and although prospected some in early days was never thoroughly examined. Mr. Shields reports that he and his partner have prospected the ground at different places along the gulch and have obtained as high as one dollar to the pan. The gold is coarse and very valuable, it being identical with the far-famed Highland dust. The gravel is ten ft deep and pays from the grass-root to the bed-rock. The gulch is admirably situated for mining, there being sufficient fall to work the ground with hydraulics. At present there are 1,000 inches of water in the creek, and this volume will be increased to 4,000 inches in the spring. Mr. Shields is confident the gulch will pay as well as any opened in the country, and further expresses the conviction that, having talked with men who visited the Ceur d'Alene country, he regards the Fish creek discovery as the most valuable of the two.

NOTES.—Inter-Mountain, Dec. 18: The Anaconda company is employing about 300 men in and around the Anaconda and St. Lawrence mines. The

important strike made some time ago in the Monton from the 400 level holds its own in good shape. Explorations in good ore are vigorously progressing. In the Bell the magnificent ore body discovered on the 400 level improves with development. The high grade copper ore body is fully eight ft wide. Operations are actively progressing in the 400 level of the Colusa. The ledge has been penetrated and an extensive body of low grade copper ore is reported. It is estimated that the upper levels contain enough ore to supply the smelter for two years. In the east end of the Magna Charta, Mr. Hall reports an extensive body of high grade ore. In some other parts of the mine the ore is of good grade but occurs in somewhat narrow streaks. On the editorial page of this issue the amount of the Lexington product for this year is estimated at \$1,400,000. This it should be understood is somewhat more than the company will realize, as the estimate is made on a basis of the market price of silver. The amount realized by the company, figuring bullion at \$1.05, will probably be between \$1,200,000 and \$1,300,000 as the result of the year's work. The financial statement of the Alice company is now being prepared, and will, we hope, prove amply satisfactory to the stockholders.

NEW MEXICO.

SHERMAN MINE.—Southwest Sentinel, Dec. 19: The ore is not of a very high grade, yet the average of it is equal to that of either Leadville or Tombstone. We have never seen any of the ore tested or assayed, but we think we would not be amiss in saying the average is not far from \$35 per ton. In fact Mr. Williams informed us that the many hundreds of tons worked in the mills here, within the last two or three years, have yielded from \$30 to \$40 per ton. Out of a dump pile of 60 or 70 tons of ore we could not break a piece that did not contain horn silver in quantity. The mine is now opened so that quite a force of men could be put to work.

GRAPHIC.—Thirteen tons of ore were recently shipped to Socorro for treatment, from the Graphic mine, in Cook's Peak district, and netted the owners \$102.75 per ton. This mine belongs to A. P. Taylor, Dick Hudson and Al Dart. This explodes the theory that the ore in that district is too low grade to pay for working.

CARLISLE.—Incident to the change of management at the Carlisle mine, the mill has been shut down. This, however, is but temporary. It will start up again about the 1st of January. We understand that the water supply at the mill has greatly increased, and it will thereby be enabled to run all its stamps on full time.

BREMEN MINE.—Silver City Enterprise, Dec. 21: The 128 tons of ore shipped from the Bremen mine two weeks since to the Socorro smelter averaged 109 1/2 ounces. The whole amount brought something over \$1,200. Billy Owens, foreman of the mine, guessed that the ore would average 110 ounces, and he came within half an ounce, which is pretty close guessing on ten car-loads of ore.

MOLLIE S.—J. C. Woodward left the city yesterday morning with a force of men to resume work on the Mollie S mine, which has, owing to litigation, lain idle for a year and a half past. The Mollie S is supposed to be one of the richest and most extensive lead mines in the Territory. It is now owned by John W. Terry, President of the First National Bank of Socorro.

BURROS.—Jack Panace closed the sale yesterday of the Blue Bell mine in the Burros. J. E. Boss, H. M. Carpenter, R. H. Wellington and M. France, all of St. Paul, Minn., were the purchasers. The consideration was \$12,000, \$7,000 of which was paid down.

SIERRA GRANDE.—Lake Valley Herald, Dec. 20: In the big cut there are only two men at work. Here the area of ore uncovered has been greatly extended and as they work south, toward the "bridal chamber" it is improving in quality, running 40 to 60 ounces to the ton. The ore body is 15 to 20 ft thick and is exposed quite a long distance. Here the ore is broken so easily that two men can keep two others busy running it out upon a tramway.

SIERRA BELLA.—This property needs a mill of its own. It has now 3,000 tons of milling ore piled on the dumps, while it is so far developed that 200 men could be put to work taking out ore, and it would be an easy matter to keep a 40-stamp mill running at its full capacity.

OREGON.

CALUMET.—Baker City Tribune, Dec. 14: Sol Center, Supt., reports as follows: I took six samples of the different classes of ore we were getting and had them assayed, and had the getting of a big assay anything to do with my selection of samples, I would have gotten greater results. I put the following assays in dollars, estimating copper at 14 cents per pound; No. 1 was a dark yellow decomposed quartz and went in gold \$10.67, silver \$1.46, copper \$27, a total of \$47.13 per ton. No. 2, a dark red decomposed quartz; gold \$1.24, silver \$4.80, copper \$42; a total of \$48.04 per ton. No. 3, gray outside, dark inside and hard; traces gold and silver, copper \$168. No. 4, bright yellow, rather decomposed quartz crystals; gold \$18.43, silver \$12.17, copper \$70; a total of \$100.60 per ton. No. 5 was of the peacock character and gave gold \$23.36, silver \$7.54, copper \$172; a total of \$142.90 per ton. No. 6, decomposed quartz looking like clay; gold \$31.13, silver \$18.17, copper \$28; a total of \$77.30 per ton.

After housing everything of value in the cabins and the deep drift, we left the mine at noon of Oct. 5th, it having been snowing and storming the four days previous, and the snow being 14 inches deep on the upper end of the plant.

NOTES.—Jacksonville Times, Dec. 21: Sargent Bros. of Brushy creek, in the Steamboat district, have their claims ready for water. They have been reeking considerably during the past few months and averaged over \$2 a day to the hand. Mining of the bed of Klamath river, which has become quite extensive, is about over for the season. Some companies have done quite well. Wm. McConnell having taken out several hundred ounces of gold during the past few months. In two weeks before quitting they took out \$4,100.

For Mining Shareholders' Directory, Stock Reports, etc., see page 13.

Geology of the Eureka District.

Mr. Arnold Hague contributes to the third annual report of the Director of the United States Geological Survey an abstract of his forthcoming monograph upon the general geology of the Eureka district. The final report, which will be illustrated by numerous plates, will be elaborate in detail, and pending its appearance the abstract referred to, which occupies 49 pages, is of great interest to scientific observers.

As Mr. Hague remarks, it is doubtful if within the province of the Great Basin there is any region of equally restricted area which surpasses the Eureka district in its grand exposures of Paleozoic formations, especially of the lower and middle portions of the series.

As the district, moreover, is one of great economic interest as the seat of an active mining industry, and has been, as well, the center of intense volcanic action, it was judiciously selected for a more careful survey and study than had heretofore been given to any region of sedimentary rocks in Nevada. Unmapped and only occasionally visited by geologists, but little had been accomplished, except for the immediate purposes of mining, towards investigating its structure or solving its many geological problems. It was known to be an exceptionally broad expanse of mountains, affording fine geological sections if properly worked out, and of special interest for the purposes of comparative study in other regions of the Cordillera. In this direction almost nothing had been done.

The monograph upon the Eureka district is purely geological in its scope, and is mainly a careful study and survey of a comparatively small block of mountains, which may be designated as the Eureka mountains, but which should not be confounded with the Eureka mining district, as several other well-known mining districts also lie wholly within this mountain area. This report upon the district will appear in two parts; one a volume of text, the other an atlas of topographical and geological maps and cross-sections, and as the text is, in great measure, explanatory of the atlas, the two should be considered as parts of the same work.

The text presents as concisely as is consistent with clearness and completeness the principal geological facts observed and such general deductions as have been drawn from their study. Accompanying the report are two special monographs, prepared by Mr. Charles D. Walcott and Mr. Joseph P. Iddings, the able assistants in the geological field-work of the survey.

The area covered by the geological and topographical survey of the Eureka district embraces a region of country twenty miles square. It is situated on the Nevada plateau, in Central Nevada, midway between the basin of Lake Lahontan to the westward and the basin of Lake Bonneville to the eastward. It lies partly in the county of Eureka and partly in the county of White Pine.

The meridian of 116° west from Greenwich passes just to the westward of the center of the examined area, and the 39° 30' parallel of north latitude crosses Ruby Hill, the seat of the present activity in precious metal mining.

On the Nevada Plateau the broad central north and south valleys, lying between meridional mountain ranges, reach an average altitude of 6,000 feet above sea level, the country falling away gradually on both sides till at Salt Lake, in Utah, the altitude is 4,250 feet, and at Carson and Humboldt Lakes, in Nevada, 3,800 feet above sea level.

In general the broader physical features of the Great Basin ranges are much the same all the way from the bold escarpment of the Sierra Nevada of California to the precipitous wall of the Wahsatch mountains of Utah, the distance in an east and west line being about 425 miles. They form long, narrow mountain uplifts with sharply-defined limits, rising with more or less abruptness above broad intervals of desert. In width they seldom measure more than eight miles, but frequently extend for more than 100 miles in length, with serrated peaks and ridges rising from 2,000 to 6,000 feet above adjacent valleys. For the most part they possess a simple topographical structure and a simple drainage system. They are characterized, more especially the lower ranges, by absence of trees, and in many cases are nearly bare of all vegetation, presenting rough, rugged slopes of naked rock.

On the higher parts of the plateau the ranges, reaching a greater altitude, partake more of an Alpine or sub-Alpine character. Precipitation of moisture is more abundant, as seen both in the more frequent rains of summer and snow of winter. A greater precipitation produces larger and more frequent streams, and a continued moisture favors a varied vegetation—the spurs and ridges being more or less covered with dwarfed and stunted forest growth.

These characteristic features distinguish the ranges of the Nevada plateau from those of Lake Lahontan and Lake Bonneville basins, which present a more arid and weird aspect. A striking feature of nearly all these ranges is their isolated position, only a few of them presenting outlying spurs or low lines of rolling foothills. Occasionally inferior ridges stretch diagonally across valleys connecting distant

ranges, and still more frequently outbursts of volcanic rocks in irregular flows serve to unite, in confused masses, bodies of sedimentary formations otherwise distinct.

The East Humboldt mountains, midway between the Sierra and the Wahsatch, form the most prominent range in the Great Basin. They present not only by reason of the greater number of rugged and commanding peaks—many attaining an elevation over 11,000 feet above sea level—but by their broad, massive proportions, long-unbroken ridges, and Alpine character, the boldest uplift on the Nevada plateau. Next west from the Humboldt occurs the Diamond range, followed by the Pinion range, with the broad Diamond valley lying between them. Southward the southern extremities of these two ranges enter the Eureka district and form a part of its mountainous region.

On the plateau, among the more marked exceptions to the long, narrow ranges which rid the surface of the country may be mentioned the Roberts Peak Group, connecting the Wahsatch with the Pinion range, the White Pine mountains, and the subject of the present report, the mountains of the Eureka district.

The Eureka district forms a rough mountain block standing out by itself, except for its narrow connections with the Pinion and Diamond ranges, almost as completely isolated from its neighbors as the longer parallel ranges. As a mountain mass, however, it has never received any distinct appellation which would include all its members, it being made up of portions of several ranges and short uplifted blocks so intimately connected and insculpted as to form both topographically and geologically a single group hemmed in on all sides by the characteristic detrital valleys. To the north, Diamond valley extends for over 40 miles in an unbroken plain, the lowest part of the depression being covered in winter by a broad sheet of water, which, upon evaporation, presents during the greater part of the year a hard level floor, strongly impregnated with salt. To the south of the district lies the broad basin of Fish Creek valley, connecting with Newark valley on the east side of Diamond range, while Antelope valley cuts off the Eureka district on the west side from the neighboring mountains.

It is doubtful if any area of equal extent in Nevada possesses more varied physical features with such strongly marked contrasts. In close proximity may be seen long serrated ridges, broad summits, gently inclined tables of nearly horizontal sedimentary beds, with abrupt escarpments along canyon walls, and highly tilted strata in rough irregular spurs. And as might be expected in a country made up of individual blocks and parts of ranges and so interlocked as to form one broad mass, the region is characterized by broad shallow basins, long narrow ravines and winding valleys, presenting a more than ordinarily accidented surface with an intricate structure. Above the broad base of the surrounding sage-brush valleys, which have an altitude of 6,000 feet above sea level, rise many prominent peaks from 2,500 to 4,500 feet. Diamond peak, in the northeast corner of the district, at the southern extremity of Diamond range, is the culminating point, measuring 10,637 feet above sea level, and, with the exception of the high summits in the East Humboldt range, is one of the loftiest peaks on the Nevada plateau. Prospect peak, on the central ridge, and the second point in the district, measures 9,604 feet, while Atrypa peak, to the southwest on the same ridge, has an altitude of 4,063 feet above sea level. Other points are White Cloud peak, the highest point on a broad plateau-like ridge, 8,950 feet, Alpha peak 8,985 feet, and Woodpecker's peak 8,598 feet, all of them being formed of sedimentary rocks. Among volcanic mountains may be mentioned Richmond mountain just east of the town of Eureka, which rises to a height of 8,392 feet; and Pinto peak, an isolated cone to the southward, which reaches an altitude of 7,880 feet above sea level.

Up to the time of the rapid development of the mining interests upon Ruby Hill and Prospect mountain, the slopes and ridges about Eureka were exceptionally well supplied with an arborescent growth, a condition which was due partly to the number of high peaks but in great part to broad masses of mountains acting as condensers of desert moisture. To-day, so great has been the demand for wood and charcoal in the reduction of lead ores, that the mountains are as bare of trees as any part of the Great Basin. Several species of pines, dwarfed junipers (*Juniperus occidentalis*), and mountain mahogany (*Cercocarpus laevis*), which attain a height of over 20 feet, are, or rather were, the prevailing trees, but are now only found in a few areas preserved by their owners for future use, at no distant day.

Nature presents a barren, arid appearance. Vegetation is everywhere limited, and is mainly confined to bunch grasses on the mountain slopes, and sage brush in the open valleys.

As the valleys are mainly filled with coarse detrital material from mountain slopes, soils suitable for agricultural purposes occupy very small areas, and are only found in the broader basins. In the favored spots where water for irrigation purposes can be readily obtained, all the more hardy vegetables grow well, and are of excellent quality, but nearly all crops suffer from early frosts. In no sense can the country be regarded as an agricultural one, and cultivation of the soil is only remunerative to the farmer by reason of the very high prices received for his produce.

A rigorous winter, a long, hot summer, a dry

atmosphere, with a light precipitation of moisture, are characteristic climatic features of the Eureka district. In summer rainfalls are limited to showers, frequently very severe, but of short duration, and what are popularly known as cloud-bursts are by no means uncommon during late July and early August. The clouds, late in the afternoon, centering over Prospect peak, break with such force that many people caught without warning have been drowned. In July, 1874, a severe storm and flood carried off seventeen lives, and destroyed property to the value of many thousands of dollars.

During the season of Mr. Hague's field operations snow fell in the month of May no less than 8 times and again on June 10th and 11th. In summer the days are warm, the nights cool. The daily variation between the maximum and minimum thermometers was always very considerable, frequently showing a difference of 50° Fahrenheit. As early as August 30th the thermometer fell below 32° Fahrenheit, and on October 9th a light fall of snow covered both mountain and valley.

In the summer of 1864 the first locations of mining property were made in New York canyon, on the eastern side of Prospect mountain. In mining operations very little was accomplished until the season of 1869, when important discoveries were made on Ruby Hill, and active, intelligent work was undertaken. From that time forward mining operations on Ruby Hill have gone on steadily, and to-day the Eureka district is the most successful mining region in the State of Nevada. Recent estimates of the value of the ore production of the district since the first shipment of crude bullion in 1869 are as follows:

From 1869 to 1873.....	\$10,000,000
From 1873 to January, 1882.....	40,000,000
Total.....	\$50,000,000

Around this industry has grown up the town of Eureka, which is the center of population and trade for this part of the State. It is a long narrow settlement, lying in the main northern drainage channel of the mountains, and sheltered on the east side by Richmond mountain.

The Eureka and Palisade railway, 88 miles in length, connects the town with the Central Pacific road at Palisade. Branch tracks connect with the Eureka Consolidated and Richmond furnaces, the former at the lower, and the latter at the upper end of the town, and these again by a somewhat sinuous course with the principal mines, which are situated about two and one-half miles southwest of Eureka. There are an imposing well-built court house, three or four churches, and several blocks of brick stores and warehouses in the town. It supports two daily papers, which have a considerable influence and a wide circulation throughout the State.

Ruby Hill, the only other town of any importance in the district, is a flourishing place, nearly the entire population being actively engaged in mining in the immediate neighborhood.

It is built on the north and east sides of an isolated hill which bears the same name, and on which are located all the more prominent mines, including the Albion, Richmond, Eureka Consolidated, Phenix, and Jackson properties.

Mr. Hague gives a detailed description of the topography of the mountain masses in and adjoining the district, and describes their geological structure and relations. He then discusses the Paleozoic formations—Cambrian, Silurian, Devonian, and Carboniferous—and presents a lithological study of the igneous rocks of the neighborhood, which he divides into pre-tertiary and tertiary and post-tertiary. One of the most interesting points developed is the grand exposure of Paleozoic rocks, which in the aggregate reach a thickness of no less than 30,000 feet, as is shown in the accompanying section:

Eureka Section, Nevada, 30,000 feet.	
CARBONIFEROUS, 9,300 FEET.	
Upper coal measures.....	500
Weber conglomerate.....	2,000
Lower coal measures.....	3,800
Diamond peak quartzite.....	3,000
DEVONIAN, 8,000 FEET.	
White Pine shale.....	2,000
Nevada limestone.....	6,000
SILURIAN, 5,000 FEET.	
Lone mountain limestone.....	1,800
Eureka quartzite.....	500
Pogonip limestone.....	2,700
CAMBRIAN, 7,700 FEET.	
Hamburg shale.....	350
Hamburg limestone.....	1,200
Secret canyon shale.....	1,600
Prospect mountain limestone.....	3,050
Prospect mountain quartzite.....	1,500

The ore occurs between the Prospect mountain limestone and quartzite. In the Silurian, between the Lone mountain limestone and the Eureka quartzite, is a plane of unconformity.

Mr. Hague's report upon the general geology will be followed by a monograph on the features connected with the economic structure of the district, by Mr. J. S. Curtis, who will discuss more particularly the origin, mode of occurrence, and relations, of the ore bodies which have made Eureka so productive and so famous.

The remains of De Long and comrades of the Jeannette expedition have arrived at Irkutsk. The remains were borne in procession through the streets, escorted by a detachment through multitudes of people who joined the cortege. Many wreaths were placed on the coffin, and printed copies of poems describing the exploits and unhappy end of the party were distributed among the crowd. The remains will be taken to America.

The Petroleum Business.

There were seventeen barrels of petroleum hauled into town yesterday from the Puente for Mr. F. S. Eaton, at the office of the City Water Company. This oil is from two shallow wells, one only sixty-two feet deep and caved in for lack of casing, and one a little deeper with the boring tools stuck fast in it. These cheaply made wells are being pumped by an engine that is used to sink another well, which already has oil in it, but the proprietors are determined to go deeper to get lighter oil and more of it. The oil from the shallow wells is heavy lubricating oil, that is in constant demand, far beyond the supply. The reservoir of lighter oil is supposed to be of vast extent and deeper down, but the heavy oil in the shallow wells is very profitable, and should induce the making of more and larger wells for this special kind of oil.

As an instance of the great change that has come over the public mind in regard to the Puente lands, it may be stated that 800 acres of land on which these wells are located was valued two years ago at about \$5 per acre, being only adapted to pasture, making the whole value of the tract \$4,000. Yesterday the owner refused an offer of \$50,000 for the same land of hills and dales.

It is evident that the parties wishing to buy had been reading the *Herald*, and had learned of the vast possibilities of the tract with its grass, asphaltum, oil, and prospective coal mines. That is a good indication of the way the world moves in the county of Los Angeles.

A lot of casing tubes went out yesterday for deepening the well at Puente, and also a lot of tubing for the Chandler & Bower well, which is being deepened, at the new settlement of Petrolia. Mr. Snow, at the same place, yesterday sent a new engine to drill deeper in his encouraging location. Good news every week may be expected from this promising field, where land has advanced one hundred and twenty times its value in two years.

When the first great well shall begin to give up its treasures in this locality, there will be a boom like that in Pennsylvania twenty years ago. Without waiting to go down for deep or flowing wells, it is evident that shallow wells will be very profitable for the production of heavy oil alone. The new coal discoveries in this section tend also to the advancement of the values of real estate in that part of the county. —*Los Angeles Herald*.

Safety Catch for Wire Rope Guides.

At the meeting of the Manchester (Theological Society, held on Dec. 4, Mr. W. Brown exhibited and explained a model of a patent safety catch for wire rope guides. The invention has for its object the prevention of accidents to pit cages by the breakage of the winding rope. For this purpose two or more levers are placed on each side of the cage on either side of the guide rod. These levers turn on pins secured to the sides of the cage, and which form the centers upon which the levers work. The ends of the levers nearest the guide rod are provided with hinge joints, from which extend upward suitable rods, having rollers concaved to the diameter of the guide rod, with sides extending outwards, and having flat circular surfaces to insure an effectual grip on the guide rods and the inclined planes which are fixed at the sides of the cage. The opposite ends of the levers are each secured by a hinge joint to connecting rods, to which a link is attached for securing the cage to the winding rope. When the cage is suspended the rollers are drawn away from the guide rods and the inclined planes, the whole weight of the cage being supported upon the connecting rods, as well as the pins or centers of the levers, the connecting or tie rod forming the connection between the rope and these centers. In the event, however, of the rope or any of the connections breaking, the whole weight of the cage is thrown upon the centers, causing the suspended ends of the levers to fall and the opposite ends to rise with the rollers into the inclined plane and grip the guide rods, whereby the cage is held, supported by its own weight acting upon the rollers in the inclined planes, thus preventing it falling down the shaft when unattached to the rope or other connections. As an additional safeguard, springs are also employed for pressing on the levers so as to insure that they are operated quickly in being forced against the guide rods immediately upon the breakage of the rope.

ASBESTOS ENAMEL.—Powdered asbestos is used by M. Erichsen, of Copenhagen, for making an enamel or coating to be applied to pipes, walls, and so on. The powder is mixed with soluble salts, such as silicate of potash, and mineral or other colors which combine with silicic acid, so as to form a product which resists the action of oxygen, heat, cold or damp. The coating furnishes a refractory glaze, which protects the material it is applied to, whether wood, gas or water pipes, and stone or brick buildings. When applied to masonry or wood the surface of these is first washed with soap and water. In preparing the enamel the refuse asbestos only need be employed. It is also proposed to apply the coating to boilers in order to protect the plates against a too intense fire.

FOURTEEN thousand cotton operatives in Lancashire are idle, in consequence of a strike. Half the looms in Blackburn are stopped.

THE ENGINEER.

A Stone Bridge over the Mississippi.

The first stone bridge across the Mississippi river has just been completed at a point a little below the Falls of St. Anthony. It is a massive stone structure, stretching to the east across the river, curving at first slightly to the left in a graceful sweep, and then running at right angles to the stream directly to the east side landing, the whole course being 2,100 feet. The upper surface of the bridge presents to the view a smooth stone roadway, carrying two tracks on four lines of steel rails and walled in on either side by heavy blocks of stone, high enough and strong enough to prevent a train from leaving the bridge, even should it be thrown from the rail. The viaduct crosses the river with twenty-three arches and sixteen spans of 80 feet each. The material is granite and magnesian limestone. The width is 28 feet over all, and the height from the springing point of the arches to the top is 50 feet 6 inches. The cost was \$990,000. The possibility of running at full speed over it will result in reducing the time between Minneapolis and St. Paul from thirty to twenty minutes.

TUNNELING INTO A VOLCANO.—A New York Mexican commercial house is in negotiation with parties in Mexico for the purchase of the volcano Popocatepetl, up the slope of which it is proposed to construct a railroad for commercial purposes and for convenience. Near the summit a tunnel will also be seen to strike a location within the crater, where there is known to be a large deposit of sulphur which may be safely approached. A representative of the house recently visited the volcano with the French engineer, Mr. Charles Roay. A contract is said to have been made for the exportation of 50,000 tons of sulphur a year at least. It is also proposed to establish a factory of sulphuric acid for use in Mexico, selling it at \$3 a quintal of 65 degrees strength. These products of Popocatepetl will add largely to the business of the Inter-oceanic railway. The purchase of a volcano is quite a novel enterprise, and the railway up the side of the highest mountain in North America will probably be largely patronized by tourists, who would go there by the thousands annually were good facilities offered to make the trip.

TWO HIGH BRIDGES.—The assertion that the new bridge of the New York, Lake Erie and Western Railroad, four miles from Alton, is the highest railroad viaduct in the world, is disputed by *La Nature*, which claims that pre-eminence for the bridge of Garabit, France. That remarkable structure is 1,800 feet long, and near the middle of the great central arch the distance from the bed of the river to the rail is 413 feet. The length and maximum height of the Erie bridge are said to be respectively 2,051 and 301 feet.

HEAVY ENGINES AND AMERICAN RAILROAD TRACKS.—Mr. O. Chanute states that heavy "consolidation" engines do not injure the track more than the lighter engines formerly did. Trains have been lengthened from 22 cars in 1874 to 38 in 1883; and the weights hauled, from 106 to 228 tons. By strengthening draw-heads, links and pins, accidents from breaking apart of trains have been diminished, and the cost of haulage has been reduced from one cent to a half-cent per ton per mile. —*Mechanics*.

THE ARLBERG TUNNEL.—The fragments of rocks dividing the eastern and western galleries of the Arlberg Tunnel were removed on the 19th of November, in the presence of a notable assemblage. Baron Von Friedenthal, the Austrian Minister of Commerce, delivered an address in German and Italian. There was much enthusiasm manifested on the occasion. Subsequently a special train passed through the tunnel from the west.

THE MISSISSIPPI JETTIES.—The establishment of deep water through the jetties at the mouth of the Mississippi River is now bearing fruit in the character of the shipping going to New Orleans. Before the completion of the improvements for opening the mouth of the river, that city could be reached from the sea only by vessels drawing 18 or 19 feet at the utmost, but now the largest vessels can get in without the slightest difficulty.

AN IMMENSE WATER POWER.—Experts say that Broad river, at Anthony Shoals, Georgia, has a volume of 19,000,000 cubic feet of water per minute, and its velocity is 175 feet per minute, its fall in a mile and a quarter being ninety-two feet. The horse power is calculated to be 37,286, while Lowell, the finest developed water-power in the United States, has only 16,000 horse power.

There is talk of bridging the Mississippi at New Orleans, where the river is 2,400 feet wide. An engineer proposes seven spans of 300 feet each, one to be a draw. The piers are to be creosoted piles, driven in clusters, and heavily capped and eased with iron. The depth of the water will be no obstacle, as the piles can be spliced.

USEFUL INFORMATION.

What an Educated Man Ought to Know.

Ruskin says an educated man ought to know these things: First, where he is—that is to say, what sort of a world has he got into; how large it is, what kind of creatures live in it, and how; what it is made of, and what may be made of it. Secondly, where he is going—that is to say, what chances or reports there are of any other world besides this; what seems to be the nature of that other world. Thirdly, what he had best do under the circumstances—that is to say, what kind of faculties he possesses; what are the present state and wants of mankind; what is his place in society; and what are the readiest means in his power of attaining happiness and diffusing it. The man who knows these things, and who has his will so subdued in the learning of them that he is ready to do what he knows he ought, is an educated man; and the man who knows them not is uneducated, though he could talk all the tongues of Babel.

Appropos to the above, Henry Ward Beecher, in a recent sermon, made the following remarks, which have the "right kind of ring" to them: Some men think that because they have had no tumultuous experience that they are not converted. That is not the case. Where a man says to himself, "Here, I am not satisfied with my present mode of life, and I am going to change it," he is convicted. A sudden change from absolute darkness to absolute light is not necessary. All education is gradual, unfolding. A man who gets up in meeting and relates a most startling experience that he has had of sudden and complete change is not necessarily to be set down as a liar, but neither is he to be taken as a leader. I heard a man say once: "I smoked and chewed and snuffed at a terrible rate, but when I found the grace of God from that instant I never had the slightest desire for tobacco." Well, setting aside the theory that he lied—which may be uncharitable—I will say that out of forty millions of men he is the only one that could say that, and if the forty millions of men waited until they got rid of their lusts in that way they would forever wallow in them. I do not want you to imagine that here is a gospel churn into which you are to be poured and come out better. What I want to know is, are you discontented with the way in which you are living, and do you want to change? To join the church for business reasons is mean; to join the church for fear you will otherwise be damned is meaner yet. To try to indulge in everything that is low and vile in this life, and then to top off the loaf with God's sugar of mercy, is very mean.

DURABILITY OF IRON AND STEEL RAILS.—Some interesting statistics are given in the *Revue Industrielle* concerning the comparative durability of iron and steel rails, deduced from the accounts kept by the engineering department of the Grand Central Railway of Belgium. From these it appears that the failure of iron rails begins immediately after they are laid—usually from exfoliation, or in consequence of defects in manufacture showing themselves in some other way—so that the work of replacing them goes on continuously, the old being renewed by the end of 15 or 20 years. With steel rails the loss was found to be, for 12 years, almost nothing. Out of 520 rails laid in 1869 only one has been renewed up to the 1st of January, 1882, and this one had been broken by an accident; but before the year 1882 was over 257, or nearly half, the rails of 1869 were condemned and replaced with new ones. The reason for discarding the old rails was that their surface had been worn away to a depth of 13 mm., which is the limit of service adopted by the company, and the fact that half the rails laid 13 years before reached this limit at the same time is of much interest, as showing the uniformity of wear in the metal. Under ordinary circumstances the life of good steel rails would be much longer than 13 years; but in this particular case they were used upon a short piece of track, with a grade of 100 feet to the mile, and subjected to the effect of the movement of 30 heavy freight trains a day, descending the steep grade with the brakes on.

ARTIFICIAL IVORY.—The French *Chronicle of Industry*, of a recent date, gives an account of a new method of making artificial ivory from bones and scraps of white sheepskin. The bones are first soaked from 10 to 15 days in a solution of chloride of lime, after which they are washed in water and dried; they are then mixed with scraps of white leather, put in a large kettle and boiled, forming a conglomerate mass of the whole, to which is added 21 per cent of alum. As fast as any seam or froth rises to the top it is skimmed off, the boiling being continued until the liquid clarifies. The proper coloring matter is now added and the boiling stopped. The liquid, which has now partially cooled, is strained through a cloth into a cooler, where it is left until it has hardened to such a degree that it will not pass through the meshes of the cloth. The mass is then further dried upon frames, after which it is hardened by placing in a cold alum bath for 8 or 10 hours. The total amount of alum required in the process is equal to one-half the weight of the finished ivory. The ivory, when taken from the alum bath, is washed in clear

water and allowed to dry in the air. It is said that this artificial product is easily worked, and takes as high a polish as real ivory.

CLEANING BRASS.—The government recipe for cleaning brass, used in the arsenals, is said to be as follows: Make a mixture of one part common nitric acid, and one-half part sulphuric acid in a stone jar; then place ready a pail of fresh water and a box of sawdust. Dip the articles to be cleaned in the acid, then remove them into the water after which rub them with sawdust. This immediately changes them to a brilliant color. If the brass is greasy it must be first dipped in a strong solution of potash and soda in warm water; this cuts the grease so that the acid has the power to act. The *Manufacturer* says that rusted steel can be cleaned by washing with a solution of half an ounce of cyanide potassium, in two ounces of water, and then brushing with a paste composed of half an ounce of cyanide potassium, half an ounce of castile soap, an ounce of whiting and sufficient water to make the paste. —*Cornwall Reflector*.

TO CLEAN MIRRORS.—Take a newspaper or part of one, according to the size of the glass. Fold it small and dip it into a basin of clean cold water; when thoroughly wet squeeze it out in your hand as you would a sponge, and then rub it hard all over the face of the glass, taking care that it is not so wet as to run down in streams. In fact, the paper must only be completely moistened or dampened all through. After the glass has been well rubbed with wet paper, let it rest for a few minutes, and then go over it with a fresh, dry newspaper, folded small in your hand, till it looks clear and bright, which it will almost immediately and with no further trouble. This method, simple as it is, is the best and most expeditious for cleaning mirrors, and it will be found so on trial—giving a cleanness and polish that can be produced by no other process.

TO TIN A NEW SOLDERING-IRON.—The old fashioned way is to file your iron or copper on the point into the shape you want it, put it into a clean fire and heat it until it will melt solder easily, wipe it clean and rub it on a pine board with rosin and solder until the point is tinned as you want it. The new way is to heat as above and wipe clean, then apply soldering fluid (made from zinc dissolved in muriatic acid), to the point where you want the tin, and rub it on a board with solder as above.

GOOD HEALTH.

How to Reduce Fat.

We copy the following, with some slight omissions, from an editorial in Dr. Dio Lewis' monthly:

I have called to consult you about the strangest thing in the world. I will tell you all. I am twenty-three years old. When I was nineteen I weighed one hundred and twenty-two pounds; now I weigh two hundred and nine; I am filling up with fat. I can hardly breathe. The best young man that ever lived loves me, and has been on the point of asking me to marry him; but of course he sees I am growing worse all the time, and he don't dare to venture. I can't blame him. He is the noblest man in the world, and could marry any one he chooses. I don't blame him for not wishing to unite himself to such a great tub as I am. Why, Doctor, you don't know how fat I am. I am a sight to behold. And now I have come to see if anything can be done. I know you have studied up all sorts of curious subjects, and I thought you might be able to tell me how to get rid of this dreadful curse.

She had been talking faster and faster, and with more and more feeling (after the manner of fat women, who are always emotional), until she broke down in hysterical sobs.

I inquired about her habits—table and otherwise. She replied:

"Oh, I starve myself; I don't eat enough to keep a canary bird alive, and yet I grow fatter and fatter all the time. I don't believe anything can be done for me. We all have our afflictions, and I suppose we ought to bear them with fortitude. I wouldn't mind for myself, but it is just breaking his heart; if it wasn't for him I could be reconciled."

I then explained to her our nervous system, and the bearing certain conditions of one class of nerves has upon the deposition of adipose tissue. I soon saw she was not listening, but was mourning her sorrow. Then I asked her if she would be willing to follow a prescription I might give her.

"Willing? Willing? There is nothing I would not be willing to endure if I could only get rid of this horrible condition."

I prepared a prescription for her, and arranged that she should call upon me once a week, that I might supervise her progress, and have frequent opportunities to encourage her. The prescription which I read to her was this:

First. For breakfast, eat a piece of beef or mutton as large as your hand, with a slice of white bread twice as large. For dinner, the same amount of meat, or, if preferred, fish or poultry, with the same amount of farinaceous

or vegetable food in the form of bread or potato. For supper, nothing.

Second. Drink only when greatly annoyed with thirst; then, a mouthful of lemonade without sugar.

Third. Take three times a week some form of bath in which there shall be immense perspiration. The Turkish bath is best. You must work, either in walking or some other way, several hours a day.

"But, Doctor, I can't walk; my feet are sore."

"I thought that might be the case, but if the soles of your shoes are four inches broad, and are thick and strong, walking will not hurt your feet. You must walk or work until you perspire freely, every day of the week. Of course you are in delicate health, with little endurance; but as you have told me that you are willing to do anything, you are to work hard at something six or seven hours every day."

Fourth. You must rise very early in the morning, and retire late at night. Much sleep fattens people.

Fifth. The terrible corset you have on, which compresses the center of the body, making you look a great deal fatter than you really are, must be taken off, and you must have a corset which any dressmaker can fit to you—a corset for the lower part of the abdomen, which will raise this great mass and support it.

"This is all the advice I have to give you at present. At first you will lose half a pound a day. In the first three months you will lose from twenty to thirty pounds. In six months, forty pounds. You will constantly improve in health, get over this excessive emotion, and be much stronger. That you may know exactly what is being done I wish you to be weighed; write the figures in your memorandum, and one week from now, when you come again, weigh yourself and tell me how much you have lost."

I happened to be out of the city and did not see her until her second visit, two weeks from our first meeting. It was plain when she entered that already her system was being toned up, and when we were again in my private office she said:

"I have lost six and a half pounds; not quite as much as you told me, but I am delighted, though nearly starved. I have done exactly as prescribed, and shall continue to if it kills me. You must be very careful not to make any mistakes, for I shall do just as you say. At first the thirst was dreadful. I thought I could not bear it. But now I have very little trouble with that."

About four months after our first meeting, this young woman brought a handsome young man with her, and after a pleasant chat, she said to me:

"We are engaged; but I have told my friend that I shall not consent to become his wife until I have a decent shape. When I came to you I weighed two hundred and nine pounds. I now weigh one hundred and sixty-three pounds. I am ten times as strong, active and healthy as I was then, and I have made up my mind, for my friend has left it altogether to me, that when I have lost ten or fifteen pounds more, we shall send you the invitations."

As the wedding day approached she brought the figures one hundred and fifty-two on a card, and exclaimed, with her blue eyes running over: "I am the happiest girl in the world! and don't you think I have honestly earned it? I think I am a great deal happier than I should have been if I had not worked for it."

The papers said the bride was beautiful. I thought she was, and I took a sort of scientific interest in it.

We made the usual call upon them during the first month, and when, two months after the wedding, they were spending an evening with us, I asked him if his wife had told him about my relations with her avoirdupois? He laughed heartily, and replied:

"Oh! yes, she has told me everything, I suppose; but wasn't it funny?"

MILK AND INFECTIOUS DISEASES.—The sanitary inspector who investigated an outbreak of typhoid fever in a populous London district traced the epidemic to a dairy farm where the vessels used for milk were washed with water from a well that had been contaminated by the drainage from a cesspool. In the houses of those who worked on the farm there had been cases of the fever, and the theory was that the milk had been infected with disease germs. Wooden pails are used in England for milking, and naturally furnish a better lodgement for germs than the tin pails used in this country. It is reported that a similar outbreak has occurred at Port Jervis, N. Y., and the milk from a certain farm is supposed to be the spreading cause, since 56 out of the 75 persons attacked were supplied with it. How it became infected is being studied by chemists and sanitarians. Proper sanitary precautions at all times and extreme vigilance during the prevalence of disease on the farm would banish such outbreaks. Too much care cannot be exercised in the disposal of the excreta from persons suffering from typhoid fever. Under favorable conditions the germs are washed by water, which will carry them along with it; if allowed to dry, they permeate the air—in both cases endangering health. Burying deep in the earth is not a sure way, since they will not lose their power in years. Burying seems the most reliable method of destroying them. —*Scientific American*.

Mexico, Oregon and Utah, 4-5.

THE ENGINEER.—A Stone Bridge over the Missis-

Anderson's Concentrating Mill.

(CONCLUDED FROM PAGE 1.)

vators or sluices for carrying tailings to and
from the machine. The mode of operation is
to clear the valve of the upper pan, thereby
saving the floured quicksilver and amalgam in
the tailings, separate from the concentrates;
also amalgamating to a certain extent. The
lower pans do the concentrating; the concen-
trates are discharged continuously by regulat-
ing the valves in the bottom of the pan, or as
desired.

For placer and fine gold diggings the machines
are on wagons and run by portable engines with
elevators for supplying machines and conveying
tailings to a suitable dump. All the pans are
charged with mercury, the valves being securely

crushed to pass through 60, 30 and 20 mesh
screens. The crushing goes on gradually
through rock-breakers and rollers; and the ores
are screened after each crushing whilst passing
from the rock-breakers and through the rollers,
which is done to prevent the "sliming" of the
soft metal in the ores. Each concentrating ma-
chine works the different grade of screenings—
One the 60; one the 30; and one the 20. The
valves in the bottoms of the pans are regulated
to discharge the heavy materials continuously,
or as desired. The capacity of a mill like this
is 150 tons per 24 hours.

The engravings show the arrangement of the
mill, and are sufficiently clear for any one
familiar with this class of machinery to follow
the operation. The ore is dumped from wagons
or cars through the floor of the tank room, pass-

of the lower rock-breaker is fed into the ele-
vator conveying it to the revolving screen and
crushing rolls by an adjustable automatic feeder,
which is regulated at will to any desired amount
of feed. The upper rock-breaker crushes the
coarser rock, which falls to the lower rock-
breaker and is re-crushed. After crushing in
the rock-breaker the ore is screened by a re-
volving screen—wire cloth. The upper ends of
the inclined revolving screens are 60-mesh, the
middle 30-mesh, and lower ends 20-mesh. The
coarser ore that does not go through the screens
falls from the lower ends to the crushing rolls,
where it is re-crushed and elevated to the next
revolving screen and screened as before, falling
to the crushing rolls, where it is crushed still
finer, and elevated to the next revolving screen
and screened as before, falling to crushing rolls,

closed. At will the valves can be opened, the
mercury and gold discharged and strained
through canvas or chamois skin, freeing the
gold from the mercury; then the mercury can
be returned to the pans. The capacity of ma-
chines of this class is 100 cubic yards per 24
hours.

The Crushing and Concentrating Mill.

They may be used for silver, copper, lead,
platinum, tin, antimony, cinnabar and sulphuret
ores. The machines are run in combination
with crushing rollers and Blakes's rock-breakers.
Mr. Anderson recommends two rock-breakers,
15x10; three sets of crushing rollers, 30x12;
four elevators; four revolving screens; three
concentrating machines; grizzly screens; two
automatic feeders; 80-horse power Corliss engine
and four boilers, 54x16. The ore should be

ing down and screened by the grizzly rods, the
coarse ores passing to the floor of the upper rock-
breaker, and the finer ores screened through the
grizzly rods are received by an ore bin under
the grizzly. The fine ores in the bin are fed by
an automatic ore feeder to the elevator convey-
ing the ore to the lower rock-breaker, where
it is crushed and falls to a self-adjusting hop-
per underneath the rock-breaker, which is in
connection with the automatic feeder of the ore
bin. When an over-regulated amount of ore is
in the hopper it lowers one-quarter of an inch,
thereby throwing the automatic feeder at ore
bin out of gear, and stopping the feed to the
rock-breaker.

As the ore is worked from the hopper it re-
turns to its former position, and puts the feeder
at the bin in motion. The ore from the hopper

where the crushing is completed, this set of
rolls being adjusted to run closely together.

Underneath each revolving screen there are
three hoppers for receiving the screened ores.
The boppers are connected by spouts uniting
the 60 mesh screens, the 30, and the 20 mesh
screens, thereby keeping the different grades of
screenage separate from each other. Water is
supplied to the bottom of the elevators leading
to revolving screens, and is also trickled
through perforated gas pipe over screen wire of
the revolving screen, and a certain amount of
water is supplied to each set of crushing rolls
as desired. The water supply of the mill is
preferably passed through the heater of the
boiler room, heated by exhaust steam of the
engine, and thence to the tanks on the upper
portion of the mill. From there it is distrib-

uted. Each concentrating machine works the different grade of screenage; one the 60-mesh, one the 30, and one the 20-mesh screenage.

The concentrated metals and ore are conveyed from the machines by sluices to distributors at settling tank, which can be adjusted to convey the concentrate to any desired vat or tank. After settling a desired time the water can be drawn off from the concentrate by removing the plugs in the holes of the vats. The concentrates are then shoveled into cars and conveyed to sacking and shipping rooms, or to reduction and refining works. The tailings from the concentrating machines are carried away by sluices.

The object of screening after each crushing is to prevent the "sliming" of the soft metals in the ores. The crushing goes on gradually until the ores are freed of the soft metals. Then the crushing is forced to completion.

Mr. Anderson furnishes the following estimates of cost of operating this mill for

Mills and Mill Sites.

As a matter of reference for mill men and mill owners, we have selected from all available sources, and present in condensed form, the various laws, rulings and decisions on the subject of mills and mill sites.

Mill sites may be located under the provisions of the mining statutes, and if located should be recorded in the customary manner. Section 2,337 of the U. S. Revised Statutes provides that "where non-mineral land not contiguous to the vein or lode is used or occupied by the proprietors of such vein or lode for mining or milling purposes, such non-adjacent surface ground may be embraced and included in an application for a patent for vein or lode, and the same may be patented therewith." It has been uniformly construed by the Land Office that land contiguous only to the surface ground of a lode claim was not within the prohibition named, and this would ordinarily oc-

stands upon equal footing, and a late appropriation for mining purposes is not good against a prior appropriation for a mill.

A person who has built a mill on a stream and appropriated a part of its water to propel machinery does not lose his prior right over one who has claimed the water below him for mining purposes by a sale of his interest in the water of the stream to be used in a ditch above.

Where certain persons subscribe money toward building a quartz mill, in which all the subscribers were interested, and the subscription paper, without naming any payee, provided that the money was to be paid in such manner and at such time as a majority of the subscribers might order, a Nevada court holds that the subscription was for the mutual benefit of all the subscribers.

Amalgamating machinery in a quartz mill, pans, bottoms, etc., have been held to be realty, and as such cannot be treated as personality on

Hauling quartz to a quartz mill is "performing labor for carrying on the mill," and gives the laborers a lien on the mill.

Where a mechanic's lien on a quartz mill describes the land around the building on which a lien is claimed, in these words, "with such convenient space of ground around the same as may be required for the convenient use and occupation thereof," the description is sufficient; but it is proper for the court, by its decree, to define the amount and extent of land connected with the building which is properly subject to the lien; and if the decree follows the description in the lien, it is doubtful whether the purchaser will acquire any land beyond that covered by the building.

James and Hill were the owners of a quartz crushing mill with some vacant land adjoining. They leased the vacant land to Farrington & Mier, proprietors of neighboring amalgamating works, and agreed to crush the ore for the amalgamating works for \$5 per ton, to place it

SIDE ELEVATION OF ANDERSON'S CONCENTRATING MILL WITH SIDE REMOVED TO SHOW ARRANGEMENT OF MACHINERY.

twenty-four hours: Two firemen, \$6; 2 engineers, \$8; 4 men, concentrating tanks, \$12; 2 men, concentrators, \$8; 2 men, rock-breaker, \$6; 2 roustabouts, \$5; 1 superintendent, \$15; 1 team, \$2; 6 cords wood, \$36; oils and incidentals, \$10; total, \$108. Capacity of mill for 24 hours, 150 tons; cost of crushing and concentrating, 72 cents. Mr. Anderson has carefully figured out the lumber, materials, etc., for a mill of this capacity. The lumber for the engine, boiler and tank rooms would be 43,974 feet; for the crushing and concentrating rooms, 62,663 feet; for the ore house and tank room, 33,566 feet; total, 140,203 feet. It would also require 74,000 shingles, 28,000 brick, and other things according to position. Mr. Anderson sends us also complete specifications for machinery, hardware, belting, etc., for a mill such as we have described. All these figure up in weight 174,858 pounds, or about six carloads.

THERE is a mining "boom" in the vicinity of Nashville, El Dorado county.

cur where the mill site is located contiguous to the side lines of the surface ground. Where a mill site abuts against the end of the lode it is not subject to purchase and entry.

The Mining Act of 1872 provides for patenting—1, lode claims; 2, placer claims; 3, mill sites; and 4, lode claims and mill sites, and the plat and field notes of either of these classes of claims must show an expenditure of not less than \$500 on the claim in actual labor or improvements.

When a party applies for a lode claim and mill site in the same application the law does not require that \$500 shall have been expended on the mill site, but on the lode claim only.

A notice of appropriation of a right of way for a water ditch is not a notice of the appropriation of the land on the sides of it, nor of a mill site in connection with it.

The location of a mine site is not an appropriation of water for purposes of the mill site. The appropriation of water for all purposes

account of contract between parties.

Boilers and engines in a quartz mill erected by a tenant are trade fixtures which he has a right to resume during tenancy.

The interior of a fixture in a dwelling is actual and permanent fastening to the freehold, but this is not a criterion to a fixture in a manufactory or a mill.

Mill sites must be non-mineral in character. Mill sites pass to a railroad, if located on a railroad section after the grant to the railroad took effect.

An applicant for a mill site, on which a lode exists claimed by other parties, may file an abandonment of the lode claim, and will secure a patent for the balance of the mill site.

Work done on a quartz mill and work done in a quartz mine is work on two different parcels of property, and the lien upon each cannot by agreement be apportioned arbitrarily between them, although done under one original contract.

on the ground leased, and also furnish motive power to the amalgamating works. After the arrangement James became a partner in the firm of Farrington & Mier, in the amalgamating works. In a suit the court held that neither the lease, the contract, nor the association of James made Hill a partner in the amalgamating works.

Right to water acquired by appropriation may be transferred like other property, and the transfer of a mill carries its water privileges.

The interest in water acquired by one who locates on the bank of a stream and appropriates its waters for machinery, is not property in the water as such, but the right in the momentum of its fall at the point of location, and to the flow of the water in its natural course above.

It is said that mining locations have been laid for a space of five miles along the western side of Mt. Davidson. It might astonish some if the west side should prove as rich in mines as the east side of the old mountain.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. R. Haggin or Olant and Old Abe Co., Black also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Duc's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanics in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

Special Attention Paid to Patent Law.

N. B.—Mr. J. L. Boone has been connected with the Patent business for over 15 years, and devotes himself specially to Patent litigation.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisa Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

TUBBS & CO.,

611 and 613 Front St., San Francisco.

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Olosary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commissions Codification, and gives many and improved forms. Price—Full law binding, extra paper, \$3.00.

For Sale by DEWEY & CO., San Francisco

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

F. A. HUNTINGTON,

No. 45 Fremont Street, San Francisco, Cal.

CENTRIFUGAL ROLLER QUARTZ MILL!

MILLS ERRECTED WITH ALL APPLIANCES COMPLETE.

CAPACITY AND DURABILITY GUARANTEED.

After running one of these mills on the Whidden mine, in El Dorado County, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop-stamp mill:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it, and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

SHINGLE MACHINES AND SAWMILL MACHINERY OF EVERY DESCRIPTION.

GOLD QUARTZ and PLACER MINERS'

Silver Plated

AMALGAMATING PLATES,

For Saving Gold.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 2,000 ORDERS FILLED.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought or gold separated for low percentage of result.

Mining and Scientific Press.

It is the intention of the publishers to keep the MINING AND SCIENTIFIC PRESS abreast of the times, and to make what improvements in it are possible during the coming year. Several double numbers are contemplated, the first of which will appear on January 19th, when our annual mining review will be given. The others will be duly announced.

In beginning the forty-eighth volume, which occurs with this number, we are confident that the PRESS will continue to merit the patronage it receives. All information, which is at all of a practical character, that can be obtained for the mining community, finds place in its columns. The carefully collated and condensed "mining summary," two full pages of which, in fine type, are given each week, presents in simple form, suitably arranged by States, Territories, counties and districts, all the current news. The departments of mechanical and scientific progress, and "good health," give weekly such varied items in the respective lines as are of general interest, and represent the freshest news and progress.

The "Mining Shareholders' Directory" gives, in condensed form, the business features of the mining companies. The quotations of the stock market are tabulated and the notable features commented on. The second page has, each week, correspondence from different localities on subjects connected with the industries represented by the paper. Our list of correspondents has increased, and we expect even a larger circle this year. The editorial pages treat of such live topics as are of interest to the miner, prospector, millman, metallurgist or mechanic. The subjects selected are such as are of a practical character. The engravings are mainly of appliances connected with mining, metallurgy or mechanics, and of these we have made a specialty. No journal of its class in the world gives so many engravings of this character as the PRESS. They are of special value as showing graphically all the progress in these lines. During the coming year we expect to have a great many engravings of new mining appliances. This feature alone is worth much more than the subscription to any mining man.

In short, we shall make as many improvements in the PRESS as possible, and trust that our readers will assist us all in their power. We are glad to receive correspondence, information, hints of any kind that will better our journal. We hope all our old subscribers will remain with us, and that our lists will be increased, as the better our patronage the better paper we can give.

A Primitive Gold Washer.

Auriferous sands occur on most parts of the central provinces of India. The Chutia Nagpur province includes the greater portion of the hilly region on the southwest frontier of Bengal, and is divided into a number of districts. The class who follow the trade of gold washing have different names according to locality. In some of the tribes the women wash for gold; in others not. The methods employed by the different tribes seem to be identical. Each occupies a distinct tract, and poaching on one another's streams is not indulged in. The wooden dish used for washing measures about 28 by 18 for the men, smaller ones being used by the women and children. The dish is hollowed somewhat eccentrically to a maximum depth of 2½ inches. A scraper formed of a flattened iron hook is used to collect the auriferous sand and gravel that accumulates about the rocks in the streams.

The dish when filled is placed in shallow water, and the operator working with his hands soon separates and throws aside all the coarser gravel and stones, while the agitation of the water serves to carry away all the mud and lighter portions. The dish is then balanced on the palm of the left hand, and oscillated to and fro with the right.

This serves to throw off the greater portion of the remaining gravel, and the process is completed by a circular motion which is communicated to the water in the hollow of the dish, by which even the smallest particles of foreign matter are separated, and the final result is a residue of black iron sand in which the specks of gold are readily apparent; but as mercury is not used in that part of the world all the very small and invisible gold is lost. As soon as the miner has obtained gold enough for his day's subsistence he stops work, a somewhat philosophic habit which prevents the production of Anderson bonanza kings.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.]

FOR WEEK ENDING DEC. 18, 1883.

- 290,305.—POTATO DIGGER.—A. Adam, Reno, Nev.
290,530.—SINGLE HARNESS.—C. W. Burgdorf, Petaluma, Cal.
290,316.—COOKING STOVE.—Robt. E. Burns, S. F.
290,629.—SMELTING REFRACTORY ORES.—J. Campbell, S. F.
290,404.—HOISTING CAR.—L. D. Davis, Salt Lake City, Utah.
290,410.—DIRT SCRAPER.—D. A. Faulkner, Sac.

290,509.—GATE.—J. B. Whiteman, Centerville, Oregon.
10,799.—TRADE MARK.—Geo. Simmonds, S. F.
3,774.—LABEL.—Meyer Eros & Co., S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

LOGGING LOCOMOTIVE.—John Dolbeer, S. F. No. 290,756. Dated Dec. 25, 1883. This is an apparatus in which is produced a traction and a rope-winding or hauling engine in one mechanism, which the inventor terms a logging-locomotive. It consists of an engine and boiler mounted upon a suitable frame supported upon wheels, which are adapted to run upon a track, and a gipsy or winding drum, mounted upon the forward part of the same frame, and a suitable mechanism by which the power may be applied to drive the wheels and move the locomotive along the track, or to actuate the winding apparatus. The locomotive will haul a train of log-cars to a point near the tender. The locomotive being brought to a convenient place, is disconnected and fixed by brakes or chocks, and the rope, after passing around suitably placed snatch-blocks, so that the pull from the gipsy will be nearly in direct line, is secured to the log, which is often inconveniently or inaccessible located, and it is hauled to the side of the track and loaded upon the car. When the load is complete the rope may be thrown off the gipsy and the locomotive connected, when it will be ready to haul the load to its destination.

SAFETY FENDER FOR CARS.—P. H. Cooney, S. F. No. 290,746. Dated Dec. 25, 1883. This invention is of that class intended to be applied to street-cars to prevent people from injury in getting under the car. The invention consists in a two-part swinging or hinged guard having a rubber nose-piece traveling just above the road-bed. The peculiar connection between the guard and the car-platform, the means for effecting its operation, and certain novel cushions and shields further constitute the invention. The object of the invention is to provide a guard or fender which shall be able to accommodate itself to the interior of the car-body on its springs, and to the inequalities of the road, remaining at all times in position to ward off injury to persons by preventing them from getting under the car and wheels.

BOOT.—Bernard Getelson, S. F. No. 289,525. Dated Dec. 4, 1883. This improvement in the construction of boots is more especially adapted for heavy boots, such as are used for farming or mining purposes. The leg and foot of the boot are made in the usual form. It is often difficult to remove boots when they have become wet, and efforts to do so will break down the counter. In order to render it easy to remove the boot, the inventor secures a plate between the sole of the boot and the heel layers, allowing it to extend forward far enough to be held firmly in place. The rear end projects out slightly, and forms a catch, which may be hooked over any stationary object to assist in removing the boot, which may thus easily be done. The counter of the boot is never broken, and no special boot-jack is needed.

WATER-MOTOR.—Samuel S. Richardson, Happy Camp, Del Norte Co. No. 289,560. Dated Dec. 4, 1883. The new and useful water-motor covered by this patent is intended to combine the power of the ordinary rotating spouts with that of a water-wheel by utilizing the waste of the former. It consists in a centrally-mounted water-wheel, and in a series of curved spouts, so mounted in connection with said wheel as to direct their discharge against the wheel to rotate it in one direction, while they themselves rotate in an opposite direction. The arrangement of parts utilizes the power

ordinarily wasted by the discharge of the rotating wheel, and gives a combined power which may be used for any suitable purposes.

PORTABLE LADDER FOR GATHERING FRUIT. Luther H. Titus, San Gabriel, Los Angeles Co. The invention relates to certain improvements in apparatus for gathering fruit from trees. It consists of a horizontal frame supported midway on wheels, and having anchors at the end by which it is held in place, a ladder pivoted to hangers below the frame and extending in an inclined direction upward, and a flexible tube or chute with openings at intervals through which the fruit may be introduced into it, together with a peculiar receiving bag upon the frame into which the fruit passes, and from which it may be distributed at intervals.

CENTRIFUGAL PUMP AND WATER WHEEL.—Samuel S. Richardson, Happy Camp, Del Norte Co. No. 289,559. Dated Dec. 4, 1883. This invention consists in an inverted conoidal vessel, mounted and rotating, and having a bottom aperture submerged in a liquid, and in an annular water wheel mounted above, and adapted to be rotated by the liquid thrown from the top of the conoid. The object of the invention is to elevate water for any suitable purpose, and by this operation to acquire power to whatever degree and for whatever purpose may be found practical.

WINE AND CIDER PRESS.—Henry Tyack, Grass Valley. No. 290,653. Dated Dec. 18, 1883. The improvements covered by this patent consist in various matters of construction, including principally the construction of the body or frame, and means for operating it. The following are means for operating it: The trays for catching the juice, the doors for discharging the cheese or waste, the means for opening the feed door, and a device for previously preparing or pulverizing the material. Each of the improvements has in view the general result of providing a more effective press.

BOX-COVER ATTACHMENT.—Belle Miriam Sahlein, S. F. No. 290,481. Dated Dec. 18, 1883. This is an attachment for the covers of such boxes as are mainly employed to hold hosiery and fancy small articles. It consists in a box having strips of tape, one end of which is secured to the inside front of the cover, while the other ends are secured to the inside of the box opposite, so that when the cover is in place the tapes will extend across from one side to the other. With this arrangement, box-covers cannot be misplaced.

POTATO DIGGER.—August Adam, Reno, Nev. No. 290,305. Dated Dec. 18, 1883. These improvements consist in means for driving the sifters or rakes with a positive motion, in means for adjusting the sifters, and in means for inclosing the gearing. The operation of the implement is as follows: The plow digs out the potatoes, the side runners throw them up to the sifters, which clear the earth away from them, and the cloth gathers them and prevents them from scattering. The revolution of the sifters is positive and certain.

HARNESS CHECK-HOOK.—A. C. Dietz, S. F. No. 288,696. Dated Nov. 20, 1883. This invention relates to harness check-hooks, in which is employed a wide, open ring slipping loosely through a hole in the thickened front end of the check hook, which allows the light of any strap or check-rein to be introduced, and when it is in place it is allowed to move freely through the ring and hook as the horse moves his head from side to side. The rein can not be disengaged accidentally from the check-hook.

Passing Events.

The new year was ushered in by a characteristically splendid California day, followed on the next by one of clouds and rain, perhaps more universally welcomed. The outlook for the new year is in every way favorable, and California expects that 1884 will be one of great prosperity to her thriving and progressive communities.

Men continue to push their way into the Cœur d'Alene country, notwithstanding the severity of the climate and the many difficulties to overcome. Nothing can be done there this winter, but they seem to want to be on hand by early spring.

The prospecting "boom" along the side of Mt. Davidson, which we have before noted, is one of the peculiarities of this region. A tract long neglected is now being carefully prospected, and it would be strange if the miners should open up a group of claims which would again put life and activity into the neighboring mining cities.

MILL BURNED.—A dispatch, dated January 2d, from Auburn, Placer county, says: The mill at the Belmont quartz mine, completed about a year ago at a cost of between \$30,000 and \$40,000, and one of the finest and best equipped quartz mills in this part of the State, was destroyed by fire about seven o'clock last evening.

T. F. ROWLAND, Brooklyn, New York, sole manufacturer of "Duc's Mechanical Atomizer or Pulverizer," has had erected for some time on his works one of them, which has pulverized from seven to ten tons of phosphate rock, etc., in ten hours, with thirty horse-power.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., Patent Agents.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

Mining Share Market.

Saturday being a half holiday, and Monday and Tuesday whole ones, broke up the stock business so much during the week under review that there is little to report. The market has been fairly active for a day or two; there is no special excitement to note. The northeast drift in the Sierra Nevada has got fairly started. The main south drift on the 3700 level of the Union Consolidated is making good progress. It is now thought that the main ore deposit lies to the west of this drift. Owing to the accident to the Cornish pump at the Combination shaft, operations in the middle mines received a setback of several days. Now, however, all work is going forward again in good shape. The new hydraulic pump is expected to do wonders shortly. The Imperial west drift is about entering the old levels, when miners will be put to work at exploring for ore in that mine and in the Alpha and Exchequer. Little is being done in the way of extracting ore in the Yellow Jacket, Crown Point and other Gold Hill mines at present, but it is hoped that there may soon be a better stage of water in the Carson river. When the mills can run to their full capacity, a force of men can be put to work in the mines. At the Alta the 2150 level—the lowest in the mine—is drained, and they are now preparing to resume active operations.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give their own patronage, and as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Bullion Shipments.

'Alice, Dec. 22d, \$13,482; Vienna, 22d, \$11,507; Ontario, 22d, \$3,894; Bullionville, 22d, \$19,038; Horn Silver, 22d, \$9,000; Hanauer, 23d, \$4,946; Ontario, 23d, \$46,489; Horn Silver, 23d, \$9,000; Hanauer, 25th, \$4,850; Alice, 25th, \$7,461; Vienna, 25th, \$6,086; Ontario, 25th, \$7,461; Horn Silver, 25th, \$18,000; Ontario, 27th, \$10,850; Horn Silver, 27th, \$12,000; Crescent, 27th, \$3,278; Stormont, 27th, \$3,056; Hanauer, 27th, \$4,709; Crescent, 28th, \$4,705; Hanauer, 28th, \$4,000; Ontario, 28th, \$4,126; Vienna, 28th, \$4,570; Tintic, 28th, \$4,180; Horn Silver, 28th, \$12,000; Hanauer, 29th, \$2,031; Paradise Valley, 22d, \$4,416.

If you want a Lubricant that will run any thing cool write CHARLES J. WOODBURY, GENERAL MANAGER LUBRICATING DEPARTMENT CONTINENTAL OIL AND TRANS. CO., for "Lubric." It is the best compound-grease in the market. Shipped in 5, 10 and 25-pound cans, half barrels and barrels. Warranted to give satisfaction. Observe the numbers: No. 2 is soft for outside work; No. 3 is medium soft; No. 4 is medium hard; No. 5 is very hard, where unusual lubrication is demanded. Send for Catalogue of Lubricating Oils.

An Experienced Engineer

Wants a steady situation. Is thoroughly competent. Has the best of recommendation where he has worked in Oakland. Address LOUIS KREISS, No. 468 Third street, Oakland. Refers to PHILIP ROHRBAUER, proprietor at U. S. Brewery, N. E. cor. Franklin and McAllister Sts., San Francisco.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto washed with aquaria is constantly receiving additions of new fish and other marine life. The number of sea lions is increasing, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, January 2, 1884.

At a meeting of the Board of Directors of the above named company held this day, Dividend No. 03, of twenty-five cents (25c) per share, was declared, payable on SATURDAY, January 12, 1884, at the office in this city, or at the Farmers' Loan and Trust Company, in New York.

WILLIAM WILLIS, Secretary.

OFFICE—Room No. 20, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

DIVIDEND NOTICE.

SAN FRANCISCO SAVINGS UNION,

532 California St., cor. Webb.

For the half year ending with December 31, 1883, a dividend has been declared at the rate of four and thirty-two one hundredths (4 32-100) per cent. per annum on term deposits, and three and six tenths (3 6-10) per cent. per annum on ordinary deposits, free of taxes, payable on and after January 2, 1884.

LOVELL WHITE, Cashier.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending December 31, 1883, the Board of Directors of the German Savings and Loan Society has declared a dividend on Term Deposits at the rate of four and thirty-two one hundredths (4 32-100) per cent. per annum, and on Ordinary Deposits at the rate of three and six tenths (3 6-10) per cent. per annum, payable on and after the 2nd day of January, 1884. By order,

GEO. LETTIE, Secretary.

San Francisco Pioneer Screen Works.

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to any SLOOT CUT and SLOOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the Coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Dewey & Co., Publishers.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers. \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scourification; Cupellation; Weighing the Beal; Parting; Calculating the Assay; Assay of Ore Containing Course Metal; Assay of Roasted Ore for Solubility; To Assay a Charge; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 1/2 pages, with illustrations, well bound in cloth. Price, \$1; postpaid, \$1.10. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver; Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

WATER TANKS.

NOTICE OF ASSESSMENT.

The Land Purchasers' Association.—Lo-

cation of principal place of business, San Francisco, Cal. NOTICE IS HEREBY GIVEN, that at a meeting of the Board of Directors, or Trustees, held on the 5th day of December, 1883, an assessment of five dollars (\$5.00) per share (being balance of 44th and part of 45th installments) was levied upon the capital stock of this corporation, payable immediately to the Secretary at the office of the Company, 318 Montgomery St., San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the 7th day of January, 1884, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 12th day of February, 1884, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors,

EDWARD P. GRAY, Secretary.

OFFICE—318 Montgomery St., San Francisco, Cal.

N. B.—This Assessment is to pay the taxes on the Association property for the current year.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 500 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinchley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we borrow state:

That legal service has been given that all shaking motion applied to an endless travelling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machines infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

IMPROVED FORM

—OF—

HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above cut of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "bucking," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville Foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

JOSHUA HENDY MACHINE WORKS,

49 and 51 Fremont Street,

San Francisco, Cal.

PATENTED
Oct. 11, 1881.

NEVIN'S CELEBRATED Patent Ore Roasting and Chloridizing FURNACE.

Working up to 93 per cent. of Fire Assay, using 25 per cent. less salt since July, 1882.

Number 2.

Chisholm's Improved Saw-Mills.

On this page is represented one of the improved saw-mills for which P. McG. Chisholm received a patent through the MINING AND SCIENTIFIC PRESS Patent Agency, and which received the first premium at the late fair of the Mechanics' Institute. The log is set with ease and accuracy either by hand or power. In the set works some of the advantages are: First, the head blocks or bearers correspond with the side supports and are close together; second, the setting mechanism enables the sawyer to shift the cant forward, if necessary, with accuracy and dispatch; third, the device for drawing back the uprights and set beam rapidly and easily before putting on a fresh log; fourth, the slide or set beam with its numerous attachments for receiving cants and logs of all descriptions. The carriage is run by means of a steel wire

favorable conditions, the maximum figures given above may be considerably exceeded.

The horizontal and side rests for the logs being placed at intervals of three feet to four feet for the whole length of the set works, obviates the necessity of moving the head-blocks when changing from a long log to a short one. The mills will saw a four, twelve or forty-foot log on the same carriage without making the slightest change. While the variations just named are unusual, it is a common thing for logs to vary from ten to twenty feet long, necessitating, with ordinary mills, considerable extra work in setting, or else loss of time and labor in changing the position of head-blocks. The frequent side-rests also have the advantage of insuring evenly sawed boards at the very last of every cant.

Near the end and at intermediate points in the long set works are adjustable side bearings,

patented adjustable boxes, and is properly lined with the best metal. The collars are finished with the utmost exactness, so as to insure the continued trueness of saw-plate when hung on the mandrel. Sufficient length of arbor is allowed for interchange of drive and feed pulleys, so as to run main belt outside of frame when desired.

As to feed works, the movement of the carriage is controlled by a single lever. Belting from saw arbor over differential or cone pulleys allows of three changes of feed; the friction pulley is made to revolve outside of the large flange pulley on feed shaft. Throwing the handle forward tightens a loose belt running over flange pulleys and gigs back the carriage. The saw guide can be used for either top or bottom saws, right or left hand, and is easily adjusted, the sawyer being in no danger while adjusting. In changing saws, the jaws of the guide are

Mining Not Stopped.

It must not be supposed because the debris case has been decided against the miners that mining is to cease in California by any means. It only means the hydraulic mines, and not all of them; for there are some in some parts of the State that can run a long time yet. The quartz mines, which employ the bulk of the miners, will continue to be worked, and indeed quartz mining will be more closely looked to and the industry widened, for many mining men will turn their attention to it who have been engaged in the hydraulic branch. Hydraulic mines employ comparatively few miners. As far as actual labor is concerned, one big quartz mine wants more miners than a dozen gravel mines.

The mining interests of the State have received a set back by the debris decision, and

CHISHOLM'S IMPROVED PATENT LEVER-SET CIRCULAR SAW-MILL.

rope, which winds around a grooved pulley, and over shive wheels at each end of the track, the ends being fastened near the center of the carriage, thus allowing the carriage to run one-third of its length over the end of the track. This improved method insures smooth and rapid motion of the carriage, and is a great improvement over the old rack and pinion. The spreader wheel or splitter is made thinner in the middle than near the edge, and therefore acts more quickly than other splitters, while the friction is much lessened. The roll is large and revolves on the shaft of the splitter plate. Nearly touching the saw, and opposite the same, are rolls to hold short pieces as they drop from the saw. No splinters or bits of bark can wedge against the saw plate. The shape of the rolls prevents such an occurrence, while it frequently causes annoyance in mills fitted with the ordinary bearers in frame.

The capacity of No. 1 mill, with 48-inch saw, is from 10,000 to 15,000 feet per day, of ten hours; No. 2, with 56-inch saw, from 15,000 to 20,000 feet per day; No. 3, with double circular saw, from 25,000 to 35,000 feet per day. Under

for throwing forward the small end of logs independently of each other. These are operated by a simple lever movement, so arranged that when the retaining pawl is lifted, the projecting center slide is drawn back even with the line of uprights by the falling of the lever. The taper slide is thrown forward a little in advance of the upright, and nothing more convenient and simple could well be devised for the purpose. If so desired the carriage, can be built in sections, for convenience of shipping. When an under frame is not desired the makers furnish stands and rolls to go in floor. The rolls are turned to run true, and the groove in rack castings is placed to fit the circumference of rolls, insuring a smooth and even motion of carriage past the saw. A great advantage of the rolls is that there is no chance for sawdust or pieces of bark to affect the movement of the carriage and saw cant. The stands that carry the rolls may be set on a level with the mill floor.

The mill frames are made in the most thorough manner, and are sufficiently heavy to keep all attachments in place. The arbor runs in

turned back and the saw comes off without loosening bolts or nuts. This cannot be done by any other saw guide, and is a great saving in time where saws are taken off arbor to file, etc.

The No. 1 mill is so constructed that it can be taken apart and packed anywhere over the mountains to mining regions, on pack animals, being built in sections and properly connected by rods and dowels. The wooden saw frame need have no piece to exceed six feet long, and the heaviest piece, being the friction wheel, only weighs 95 pounds. The entire mill, with wood saw frame, weighs 3,000 pounds; No. 2 mill weighs about 4,000; No. 3 mill, about 6,000 pounds. The mills are made by Chisholm & Russell, No. 429 Fourth street, S. F.

Messrs. Whitney & Marshall, of Nos. 22 and 24 Fremont street, in this city, the sole agents, keep one of these mills set up and running at their factory, and invite all persons interested to call and examine it for themselves.

A BILL has been introduced in the Virginia Legislature to prohibit the running of railroad trains on Sunday.

the bullion product of 1884 will be materially decreased. But more attention is being paid to quartz and drift mining, and more yet will be from this on. It is to be hoped, therefore, that this, with the opening of new regions in the southern part of the State, will ultimately bring our bullion product up to its old standard. At all events, California will continue to be a leading mining State. Although this blow falls heavily on many persons it is better not to consider it as an insurmountable obstacle to progress. The subject need not be considered too hastily, for it is as well to make the best of what is an unprecedented and most unfortunate occurrence. From the first it was seen to be a matter that the courts must settle, and now that the decision has come, while the decree must be complied with, wisdom indicates that the most must be made of such resources as remain within our reach.

Work on terminal facilities in Portland and Albina, and on the Oregon and California extension, still goes ahead, and no orders to stop are expected.

CORRESPONDENCE.

San Francisco and Pine Grove Mining Districts.

[Written for the Press.]

On the high dividing ridge between the Beaver valley and the Wah-Wab valley, in Beaver county, Utah, is a short range running north and south, called the San Francisco mountains, having three principal summits, differing more or less in outline and appearance, and entirely distinct in their age and character. Their altitude is medium; that is, not great. The one farthest to the south is called Grampian; this is the lowest of the three and rises about 1,000 feet above the valley. The Grampian mountains consist of stratified sedimentary rocks, which is quartzite and limestone, the middle one being granite, and the highest and northernmost of these three summits is composed of trachytes of volcanic origin. These sedimentary rocks were originally deposited under water in horizontal beds or alternating strata of sandstone and limestone, which were transformed by great heat and enormous pressure, the sandstone to vitreous sandstone or quartzite, and the limestone to dolomite marbles. This whole formation was subsequently rent asunder, one part being raised up and tilted back by powerful volcanic agencies, thus forming the mountains as we observe them and as they appear to us at present—its eastern face presenting a cross section of these strata, 1,000 feet thick, and now dipping westward into the mountain at an angle of inclination of about twenty degrees below the horizontal. That portion of the formation from which this mountain was detached either remains in its original horizontal position or sank down and was subsequently covered with the trachytes that flowed over it, and against the eastern base of the granite mountains, and the eastern and southern base of the Grampian mountains, and now forms a sort of undulating, waving plains, extending some distance eastward. The quartzite and dolomite are in contact with the granite on the north, on a line running nearly east and west, and also in contact with the trachytes on the east and the south side of the mountain. The mines are in the latter contact at the eastern base of the Grampian mountain, the foot-wall being massive layers on beds of quartzite and dolomite, and the hanging-wall trachyte, and in the center of a great mineral belt or district. The veins or lodes are distinctly traceable over the surface along the entire eastern base of the Grampian mountain to the granite on the north, a distance of about one mile and a half, the course of the veins or lodes being north ten degrees, west and south ten degrees east magnetic. The mines are at the very center or focus of this great upheaval, where all the geological evidences point to a continuance down to the deep. Adjoining the Grampian mountain on the north is another, somewhat higher and quite different in appearance, character and age, being formed of granite. Beyond this, as mentioned above, another which is the highest of the three, entirely distinct in aspect, character and formation, consisting of a pale, purple trachyte, at one time a molten and liquid, purely volcanic product.

The flow of trachyte extended along the eastern base of the above described mountains, forming more or less of a plain, and although the surface is now mostly covered with drift the trachyte appears in place at several points and forms a distinct wall to the south. We have thus a contact between the trachyte and the granite, succeeded by a contact between trachyte and metamorphosed sediments—quartzite and dolomite marbles—and in this contact occurs the bonanza, or hornsilver. All of these "contacts," if thoroughly prospected will, without doubt, produce many more bonanzas equal in value to the now renowned Hornsilver. The town of Frisco, a mile easterly of the mines, is built on an extinct crater filled with volcanic ashes and tufa. It is evident that this crater was once the valve through which the volcanic forces came directly to the surface from below through the great fissure made by the break in the limestone and quartzite. This fissure, following the contacts, forms the veins or lodes. The principal veins of San Francisco district are: The Hornsilver, which is the original location on the main lode, having several extensions north and south; Carhouate, Cove and Cove Extension; Comet, Cactus, Cyprus, Colburn, Americus, Antwerp, Bonanza, Bradshaw, Dolly Mack, Dexter, Dives, Florida, Grampian, Governor, Great Republic, Hoodoo, Jay Hawker, Tulea, Morning Star, Massachusetts, Morrison, Niagara, New Haven, Quartzite, Rosa, Rattler, Sherman, Silverapolis, Summit, Hope, Triangle, Vanderbilt, Woollett and Young America.

As it would take too much space and time to describe all of the above mines, I will here confine myself to the leader, the "Hornsilver." The vein is traceable for several miles, from the southeastern end of the Grampian mountain to the point where the dolomite gives place to granite. The width of the vein at the Hornsilver discovery is from forty to sixty feet, showing galena in places all throughout the length of the claim. The vein dips north eighty degrees east magnetic at an angle of inclination of about seventy degrees from the horizontal. The footwall of the lode consists of

quartzite and limestone beds, and the hanging-wall of partially decomposed trachytic material. From these facts it will readily be seen that the dip and also the strike must vary at different points, especially there where the softer parts—the dolomite—are more readily decomposed and eroded than the quartzite. Therefore the width of the lode varies in places. Both walls are covered with a dry ferruginous clay which serves as an indicator of the lode and the walls thereof. The hanging-wall of said lode has been penetrated for a distance of 200 feet or more. The following material is thereby disclosed: Adjoining these are twenty to twenty-five feet of clay, stained with oxide of iron, then thirty feet of tough blue clay merging gradually into a decomposed trachytic mass of a reddish gray color. The lode itself contains in its enormous vein fissure two general classes of material. The larger portion is what is termed smelting ore; this is soft and earthy, consisting of sulphate, oxide and carbonate of lead, carrying silver. The smaller portion is heavy spar (sulphate of baryta), carrying chloride of silver, sulphate of silver and ruby silver. The sparry ore is found on the side of the hanging wall in the upper part of the vein and has resisted decomposition on account of its position in the lode, and on account of the refractory nature of the material composing this kind of ore. All the other ore of this immense vein has undergone oxidation and other changes. There is no doubt, but as depth is gained, the ore will be found in its original condition—that is, in the form of sulphurets. Remarkable is the absence of wall material, so-called "horse," in the vein filling. All is ore from wall to wall, and silver bearing. This lode will remain dry to a considerable depth. Assay value of the ore is \$60 per ton; daily production, 100 to 150 tons of ore; net profits, \$20 per ton. The ore body contains 280,000 tons of ore in sight, representing a value of \$16,000,000. The amount of ore extracted up to date is 153,000 tons. Dividends paid in the past, up to date, amount to \$2,700,000.

U. S. Surveyor.

Affairs in Mexico.

[Correspondence of the MINING AND SCIENTIFIC PRESS.]

The Yellow Fever and Its Effects.

With the disappearance of the yellow scourge that afflicted the inhabitants of Guaymas last summer, the business of the place, for a time much interrupted, has gradually revived, and is just now unusually active, with a prospect of so continuing throughout the coming winter at least. The malady, though a serious detriment to business and otherwise a great evil at the time, has not been without its advantages. Admonished by this new danger, the authorities of the town adopted a variety of sanitary measures, such as causing the streets to be cleaned, improving the drainage, purifying the more filthy localities, etc., precautions that hitherto had been wholly neglected, and which, once taken, must now result in much permanent good. Being so fortified against their approach, it is not likely that Guaymas will ever again suffer severely from contagious diseases of any kind, as the place is naturally healthful and there is little fear that these self-protecting efforts will soon be relaxed. Indeed, it is probable that this awakening of the good people here will lead to the adoption of other reformatory measures designed to promote the public health, further the interests of commerce, and otherwise benefit the place. This is a new departure for our Mexican brethren; not much have they been accustomed to act in concert for the public good. Hardly ever before have they been sufficiently aroused to combine their efforts for the accomplishment of social, sanitary or similar objects. Having shown so much enterprise on this occasion, further manifestations of public spirit may be looked for.

Concerning the Business of Mining Down Here.

A subject which most interests you Californians, there is this to be said. For mere speculative purposes it is dead enough, that branch of the business having been greatly overdone. As a field for productive operations Sonora is not surpassed, if equaled by any other country in the world. I have been over a great deal of it, and speak from actual observation, or rather, perhaps, I should say, actual knowledge. But with Californians in Luck.

A company of Californians are reported to have obtained a half interest in one of the most noted of the old mines of Sonora on condition of their freeing it from water and putting up a mill for working the ore. This mine, known as the Cueva Santa, is situated in the Santa Rosa District. As to the precise locality of this district I am not advised, though I believe it lies in a range of mountains running parallel with and to the west of the main Sierra Madre, which traverses the State centrally from north to south. This company is said to be made up of practical miners—men of energy and experience who will manage the business themselves, having money enough of the iron to rehabilitate the property and outfit it with a mill and hoisting works, the latter with pumping gear being already on the ground. Certain Eastern parties had been negotiating for this mine, but your Californians managed to get in ahead of them and secure the prize. The new owners having cleared the mine of water, found in the lower

workings an ore-bearing vein averaging more than a foot in thickness, every pound of which will yield at the rate of \$400 silver, and \$100 in gold per ton. There is absolutely no waste—such, at least, is the story that comes to us here. Making due allowance for the overstatement common in these cases there would appear to be a concentrated bonanza in this Cueva mine. A number of mining sharps have lately left Guaymas for the Santa Rosa District, which lies somewhere in the mountains in a southerly direction from the town of Altar.

The Wet Season

Set in here, as usual, in the month of September, since which heavy rains have fallen in the mountains of the interior, where the precipitation is greater than near the coast. The climate of Sonora does not differ much from that of Southern California, except that the rainfall is here much greater. Our summers throughout the *Tierra Caliente*—being the strips of country lying along the gulf of California—are long and hot. The summer heat elsewhere is modified by elevation, being never oppressive in the higher mountains, though the winters there are cold, with considerable snow. Snow never falls below an altitude of three or four thousand feet. In the *Tierra Caliente* frost is unknown, oranges, lemons and other semi-tropical fruits growing and maturing there the whole winter long. A sirocco blowing from the interior sometimes visits Guaymas so hot that both men and animals seek shelter from it. It seldom continues, however, for more than twenty-four hours at a time. Though the heat here abates after sundown, and is never of the sultry, stifling kind experienced in the Atlantic States, the nights are not generally so cool as in California. In some parts of the interior a very uncomfortable degree of heat prevails throughout the entire twenty-four hours.

Guaymas, Sonora, Mexico, Dec. 15, 1883.

Systems of the Crucible Assay.*

In all the fire assays of gold and silver ores, the precious metals are collected by means of lead from which they are afterwards separated. In crucible assays the lead is produced from litharge by the action of reducers. The crucible assay is divided into two systems, either of which may be applied to any ore, but is best adapted to certain cases.

In the assay by the first system, more litharge is used than is requisite for the production of lead. The excess assists in fluxing the assay. All base metals, except the required lead, are oxidized and dissolved in the slag. This assay is quickly made, and generally gives accurate results. It has the disadvantage of requiring considerable modification of the various ores, as to the fluxes proper, and to the reducers or oxidizers by which the production of lead is controlled. Sometimes a preliminary assay is necessary.

In the assay by the second system, only enough litharge is used to furnish the required lead. All base metals except lead remain combined with sulphur, or, as arsenic and antimony, are volatilized, or combine with iron. This assay requires a longer time than the other, but presents the following advantages: The right quantity of lead may nearly always be got at once, for, although any lead which the ore may contain will inevitably come down together with that from the litharge used, yet this can be allowed for by reducing the quantity of litharge or omitting it. As litharge yields ninety-three per cent of lead, it is not difficult to make the adjustment nearly enough. Galena contains eighty-six per cent of lead, hence if the ore is nearly pure galena, but little litharge is needed. The method requires but slight modification for different ores, and may with little disadvantage be made universal. The hutton is never much contaminated by copper, as it often is in the other system unless a very large proportion of litharge is used, which is disadvantageous in some ways. The crucible is but little attacked, and the assay is not liable to boil over.

The method is especially useful for ores carrying much galena or other sulphuret, and when copper in any form is present. The writer has found it accurate for all ores, except one case of concentrated sulphurets containing gold and silver. All the gold was obtained, but scorification gave a little more silver. All crucible assays failed in this case, as also with an arsenical matte or speiss from a smelter, which also yielded only to scorification.

*From a practical work on "Assaying of Gold and Silver Ores," by Chas. A. Aaron, lately issued by Dewey & Co., S. F.

They have drained the water out of the lowest level—2150 feet—of the Alta mine, on the Comstock. The level is found to have sustained but little damage from the water with which it was so long flooded; indeed, it is in much better shape than it would have been had it stood exposed to the action of the air for the same length of time. It will not be much trouble to clean out the drifts, as they contain but little slime. It is found that most of the mud and slime is at and about the station. It is in the shape of drillings and other debris that went down the shaft. The east drift on the 2150 stands in almost perfect shape, while in the west drift are only a few spots where rock has tumbled in.

To Cheapen Mining Patents.

The White Pine *Cone* has taken up the discussion of this important subject. It is something that we have tried to call the attention of the mining press to, for the past year. It is a question that should be thoroughly canvassed and discussed. The *Cone* takes issue with our statement about extortion and robbery. We admit the expressions are harsh and rather far-fetched. But it appeared to us to be necessary to call attention to the wrongs and burdens of the prospector and miner. The *Cone* conveys the impression that it is hardly possible to cheapen the cost of patents except as far as the \$5 per acre goes. Now that \$5 is what we find the least fault with. It is the red tape necessary before the privilege of paying the government that \$5 per acre can be had.

We will start out with the assumption that the law for surveying mining claims is unjust. It is just as much the duty of the general government to survey the mining sections of the country as the agricultural portions. If the mining sections were sectionized and subdivided, the cost of surveying mining claims would be materially lessened. For instance, A has a claim. It is somewhere in the northwest quarter of section 2, T. 12 S., R. 86 west. A wishes to patent. He will have it surveyed, connecting the corners of his claim so many feet, in whatever direction it may be, to such quarter or section corners as are most accessible. He then takes or sends his plat to the Land Office, the Register designating the claim as No. —, on northwest quarter of Section 2, T. 12 S., R. 86 west. The claim may cross into different townships, sections or quarter-sections, which the plan will show, and all the Register will have to do is to number the applications and accord to them section or sections on which the discovery may be situated. The publication of intention to prove up and enter the claim can be made the same as is now required on agricultural land. After expiration of publication the owner of the claim takes his witnesses to the Land Office, makes proof of ownership, and the lawful improvements, pays for his claim and receives his patent the same as he would on an agricultural claim. By this plan all the unnecessary and cumbersome red tape machinery of asking for order of survey, posting notices, of employing attorneys and long, costly publications would be done away with. We would not have the present necessary \$500 worth of improvements reduced, but would rather, if a change is to be made, have it increased.

Here, Mr. *Cone*, is an imperfect plan to cheapen and improve the present cumbersome and costly mineral patent law. Others may suggest a better. No one can hardly suggest a worse law than the present, for almost any change that should be made would be for the better.

The Cœur d'Alene Placers.

A. E. Driggs, the well known express and stage man of this city, has returned from the Cœur d'Alenes. He confirms previous reports as to the extent and value of the new diggings and thinks the rush and excitement next spring will be unprecedented. He says the main travel into the gold fields must be from this side, on account of the swollen river which must be crossed over thirty miles by the Rathdrum route, and which will be impassable during the spring thaw. The Trout Creek route now appears to be the most feasible and will probably be the favorite trail. At present nothing is being packed into the mines. There is no grub there for sale and the miners who have camped there for the winter have laid in provisions only for their own use and will not sell at any price.—*Butte Miner*.

The latest description of the new mining region in the Cœur d'Alene mountains is this: Pritchard's gulch is 20 miles long and from 200 to 500 yards wide, the stream falling about 2 feet in 100. The slate crosses the stream at nearly right angles and the jagged slate makes natural riffles which have caught the gold. On Pritchard's gulch prospects have been found for 15 miles. The gold is worth \$16.50 per ounce. Eagle Creek is 10 miles long and from 200 to 500 yards wide. Good prospects are reported at the lower end. Beaver creek is 18 miles long. Some prospects have been found along this creek, but bedrock has not yet been found.—*Idaho Statesman*.

Such is the location of Eagle City, in the Cœur d'Alene mountains, that the sun does not shine upon it until 11 A. M., and then only for an hour, disappearing behind the mountains at noon.

The Pritchard creek (Cœur d'Alene) metropolis has 21 log cabins, in which 100 men and one woman are sheltered for the winter.

Pritchard gulch gold is worth \$18 an ounce, passing current at that figure in all commercial transactions.

Pritchard creek carries a large swift-flowing body of water, sufficient for all mining purposes, if claims should be located its entire length. The gulch is heavily timbered, many of the trees being from twelve to fourteen feet in circumference.

At Eagle City flour is worth 20 cents per pound; bacon 40 cents; sugar 75 cents; beans 40 cents; butter \$1.50; beef and venison 25 cents, with little to be had, and other necessities scarce and correspondingly high.

MECHANICAL PROGRESS.

The Cinder of Wrought Iron.

Special attention, says Professor Ledbur in *Stahl und Eisen*, translated in a recent issue of *Iron*, has justly been bestowed for years upon the determination of the carbon, manganese, silicon, etc., contained in malleable iron; but the determination of the cinder mixed with wrought iron has but rarely been the subject of investigation by chemists. And yet the quantity of cinder contained in iron affects its mechanical properties no less than many of the alloyed substances. Indeed, it may be affirmed that, at least in the wrought iron containing but small amounts of carbon—fibrous iron—silicon and manganese, where such are found, are not alloyed with the iron, but are merely present as constituents of the incorporated cinder. This cinder may not infrequently be observed in the fracture of iron, especially with the aid of a magnifying glass. If fibrous iron is splintered in the direction of the fiber, cinder may often be seen very plainly between the fibers. A more complete evidence of the presence of cinder in wrought iron is obtained if the fracture is polished and treated in the well-known manner with strong acids. In the places where cinder is present, a depression or small pit is formed in the surface so treated. Ingot iron does not show this phenomenon; wrought steel and fine-grained iron display it proportionately less, but fibrous iron appears to be covered with these small holes. I explain their origin in the following manner:

Everywhere where a grain of cinder was mixed with the iron, it was not without chemical action upon its surroundings by the repeated and continuous heating of the iron. It may be assumed that such mechanically intermixed cinder is in all cases rich in peroxides of iron, and that those peroxides already, during prolonged heating in contact with iron containing carbon, act as an oxidizing agent upon its carbon. We need only be reminded of the process of manufacture of malleable castings.

All the conditions for such a process are present. In every case there is formed round the grain of cinder an iron less able to resist chemical influences. It is well known that, as the contents of carbon decreases, iron is rendered more liable to chemical action. If the fractured surface is, therefore, treated with acids, they penetrate, in the first place, between the splinters of the cinder and the iron. The former is dissolved or drops out, and the iron then offers a great surface to the attacks of the acid. The openings rapidly increase in size, and are then seen by the eye as the small pits mentioned above.

Unfortunately, there does not exist a simple method of determining the quantity of cinder contained in wrought iron, and the reliability of the various ways proposed up to present time is not entirely unquestioned. This may be the principal reason why as yet proportionately few determinations of cinder have been undertaken. Some have proposed to heat the iron to be examined in a current of chloric gas, when cinder remains, and the metallic iron, etc., are evaporated. Others apply a solution of bromine in bromide of potassium in order to dissolve the iron and to separate it from the cinder; yet others use ammoniacal chloride of copper. Professor Eggertz uses iodine in water, and during the solution of the iron cools the beaker containing the various elements in iced water. In all cases it is necessary, if the iron to be examined contains silicon in a non-oxidized state, to treat the residuum with soda solution in the water bath, in order to dissolve the silicic acid that may have been formed.

Some Curiosities of Steel.

Eight master taps, or hobs, were made from the same bar of four-inch steel, each cut to a pitch of three to the inch, each scored, heated, hardened and drawn to temper at the same time. Six hours after the tempering one of them "exploded," or at least cracked into three pieces with a report. The fractures give to the trained mechanical eye the appearance of good steel, and show no water cracks or other evidence of previous fracture. At the same establishment where this breaking occurred, one of its most important departments is the production of taps, reamers, dies, and similar tools. It has been abundantly proved that forged taps and reamers are inferior to those made direct from the sized commercial bar, not only in their resistance to torsion, but in the retention of their integrity under the exactions of hardening and tempering; the best taps are those which are turned direct from the bar.

There seems to be a tendency of forged steel, under certain forms, to return to the shape of the original bar. This is shown especially when the forging from a square bar is flattened. Sometimes a flattened piece will curve in the hardening as though its fibers had been stretched, and, when relaxed by the heat and again placed under tension by the cooling process, contracted toward the original condensed, square form. A singular example was noticed recently. A plug gauge two and five-eighths inches wide and one and three-sixteenths inches thick was forged from a square bar, finished and hardened. After hardening it was ground to exact size by a corundum wheel, when the

ground side immediately swelled in the center almost enough to be seen by the unaided eye, but was quite apparent with the straight edge. The other face, from which the skin of hardening had not been removed, remained straight, but as soon as that had been ground it acted just as the other did and both the side faces were swelled, and so much so that the increase in thickness by the micrometer gauge was more than one-hundredth of an inch.

On treating the edges a contrary result was produced; each edge face became concave, so that when the grinding was completed the plug had two opposite convex sides and two opposite concave edges. The plug was then annealed and redressed to truth; then rehardened and re-ground with the same results as at first. A second time it was annealed, trued and then case-hardened, but even then it continued its perversity, and it is to be kept as a curiosity as it is, unless it is decided to saw it in two and inspect its interior.

The most vexatious thing about these "quercities" is that no theory that bears the test of practice has, so far, accounted for them. If the "reason why" could be discovered, the causes could be removed and the working of steel be made an exact and certain art. Still, there has been great progress made in this direction during the last twenty years; the percentage of loss in hardening and tempering steel has been reduced to a very low figure. These improvements have been owing to the greater uniformity in the character of the steel produced as well as to the greater skill in its after manipulation. We may not despair of yet being able to make the production of hardened steel articles as even and certain as those from any other material.—*Scientific American*.

A NEW WELDING FLUX.—Jean Laffitte, of Paris, has obtained French and American patents for a new welding material. His claims are specified as follows: 1. A welding material composed of twenty-five parts, by weight, of borax, a paper or metallic support, and sixty parts of metallic filings of the same nature as the metals to be welded, and made by first melting the borax; second, immersing the support in the fused borax; third, smoothing the same by passing it through pressure rollers; fourth, sprinkling its two faces with the metal filings; fifth, heating the sheet in an oven, and sixth, passing through pressure rollers, as and for the purpose described. 2. A welding material composed of borax and of metallic filings of the same nature as the metals to be welded, mixed with the fused borax, and in the proportions substantially as set forth, and then rolled out into sheets of about one sixteenth of an inch thick, as and for the purposes described. 3. The welding sheets made as hereinabove described, and then coated with a layer of gum-lac or other appropriate varnish, as and for the purpose set forth.

HARDENING STEEL.—If a piece of steel be hardened and lifted from the water before it is cold, a crack or flaw may be the result. The reason is that the outer surface being very hard and the inside hot, expansion commences and a breakage of the hard chilled surface is the consequence. More tools are ruined by overheating, cold-hammering and over-tempering than can be redeemed by all the new recipes that have been invented. Use only steel that is good and suitable for the tools to be made, and stick to it. Find by a few trials the lowest heat that will harden it in pure water at seventy degrees, or ordinary shop temperature. If steel is hardened at the lowest heat, the temper will require drawing very little, i. e., to a pale straw, full straw or brownish-yellow, but not deeper unless for wood working tools with thin cutting edges, when a full brown may be desirable.—*Sewing Machine News*.

POLISH AND CASE HARDENING.—The finer the polish which is imparted to the surface in case hardening the better will be the results. The art is a very useful one, and should be thoroughly understood by every smith and worker in metal. The process is very simple. The articles are placed in some air-tight receptacle, generally an iron box, but often a pipe, which can be turned, and therefore admits of the more uniform application of heat. The receptacle is filled with coarse charcoal powder and exposed to a cherry-red heat for twenty-four hours. If a hard surface one-eighth of an inch is desired, but from four to five will be long enough to make a good surface of steel.—*Sewing Machine News*.

A NEW PROJECTILE.—Krupp has recently taken out a patent for a flat-headed projectile, which novel form was given to it with a view of preventing its gliding off on striking the armor plate of a vessel at a great angle of inclination. The form has further been adopted with the object of penetrating a ship's armor below the water line, an operation hitherto attended with but little success, owing to the pointed head of the shot. In order not to cause a loss of velocity, a point of wood or thin iron plate is attached, which, on striking, is immediately shattered, but, at the same time, being filled with oil, which is to "grease" the projectile, is said to increase its power of penetration.

CHILLING IRON.—Dr. Wedding points to the fact that when melted iron is allowed to chill the first crystals which form are nearly pure iron. He suggests that, by repeatedly crystallizing the iron, a metal of high character may be obtained from poor pig iron.

SCIENTIFIC PROGRESS.

Vegetable Evaporation—Impoverishment of Land.

M. Deherain, in his interesting discourses upon the exhaustion of the soil by cultivation, makes some statements that are striking and suggestive.

In speaking of the evaporation of water from the leaves of plants, he says that in one hour, exposed to the sun, a leaf of barley exhales a weight of water equal to its own; and calculating upon these figures, 2.5 English acres of maize will lose, under the same circumstances, 25 cubic meters of water. Hales, an English observer, has said that 2.5 English acres of cabbages lose, each day, 20 cubic meters of water; and Lawes and Gilbert, in their studies on this subject, proved that a plant which has formed one kilogramme of substance within itself has carried in circulation through its tissues 250 to 300 kilogrammes of water.

Humus or decayed vegetable matter, is the body which is most efficacious in retaining and keeping in a pure state the terrestrial waters. It can absorb an amount of water greater than its own weight, holds it more tenaciously than clay and infinitely better than sand. Analyses show that humus abounds in the prairies, or unused lands, and that it diminishes greatly in cultivated districts.

M. Boussingault found in a pasturage of Argentina, in a kilogramme of soil, 40 grammes of carbon belonging to organic matters, and only 28 and 24 in the same quantity of cultivated land. M. Trucot found 10, 12, 14, 18 grammes of carbon in the districts of Limagne and Auvergne, which were highly cultivated, while he reports 110, 120, 148 grammes in the prairie lands of the high mountains which were roamed over by cattle, but never received fertilizers. The reasons for this difference are not difficult to determine. In the unused fields the earth is not broken up or exposed to the oxidizing and destructive action of the air, and the decaying roots, sprays, and scapes of the grass or herbs constantly increase or maintain unchanged its percentage of humus.

M. Deherain has demonstrated the cause of this loss. He divided his experimental land into parcels and devoted many of them to a continuous cultivation. Some from 1875 to 1879 have borne potatoes, others corn, others each year, beets. In 1878 the land planted with maize, in one kilogramme contained 16, 15, 13 grammes of carbon; at the end of 1879, eighteen months later, the same weight of soil gave 14.4, 10.4, 13.1, 12.3, and at the end 1881 the amount had been reduced to 8.0, 7.6, 6.1 grammes of carbon per kilogramme of soil.

In 1879 he examined the land planted with beets and corn, having yielded three harvests of beets and one of corn, and found the quantity of organic substances oscillating around 13 grammes per kilogramme. He then sowed this ground with sainfoin, which remained undisturbed for three years and yielded excellent crops. At the end of the experiment he found the amount of carbon per kilogramme of soil had scarcely changed, being in fact 11.4, 13.0, 13.3, 12.8, 12.1, or a mean of 12.5, contrasting to great advantage with the reduced amounts in the harrowed and turned up grounds.

Apart from the reduction of organic matter in soils upon being turned up, the oxidation which removes the organic matter M. Deherain attributes to chemical change, by contact with air and to fermentation, but also largely to the activity of living organisms, plants and animals; for he observes, "The soil is not simply a mass, porous and inert, of clay, sand and humus, but rather a center of organic activity."

Although MM. Schlessing and Muntz have shown that the formation of carbonic anhydride goes on in a sterilized soil, it is yet probable that microscopic germs and other living occupants of the earth are the principal agents in its production ordinarily.

These inferior beings play an important role, and MM. Lawes, Gilbert, and Warrington have shown that the mushrooms, which at some seasons appear in such numbers, decompose and assimilate large quantities of the organic contents of soils. The well known "fairy circles" in fields are due to a luxuriant growth of grass following the disappearance of the mushrooms, which first formed them. These chemists found that outside of these circles the ground contained 3.30 per cent of combined carbon, while within and after the occupancy of the space by these parasites, the samples yielded 2.78 per cent. This difference corresponds to almost 9,000 kilogrammes of carbon to 1 hectare (2.5 English acres) of land.

TEMPERATURE OF THE SUN.—In a recent lecture on solar physics at the Royal Institution, Sir Wm. Siemens gave his reasons for setting the temperature of the photo-sphere of the sun at about 2,800 degrees C., instead of about 10,000 degrees, where Rosetti and other late investigators put it. He agrees, in this lower estimate, with Violle, St. Clair, Deville and Sir William Thompson, and thinks the solar temperature can not much, if at all, exceed that of the most powerful electric arcs. He recognizes fully the fact that a temperature higher than 3,000 degrees C. would be absolutely conclusive against his theory that the solar heat is due to the recombination or burning of compound gases at the surface of the sun. He

bases his estimate of the solar temperature upon three foundations: First, the behavior of a carbon rod and a small gas flame in the focus of a reflector exposed to the sun; second, on a comparison between the spectra of various lights—for instance, the Argand burner, an incandescent lamp, the electric arc, and the sun itself, as observed by Langley on Mount Whitney; third, upon experiments on the relation between radiating power, made by means of a long platinum wire heated by an electric current.

THE SUNSET COLORS.—The earthquake theory seems to be the prevailing one, among scientists, to account for the sunset colors which have been so remarkable for the last few weeks. A correspondent of the *Scientific American*, in supporting this theory, says: The forces there in operation—unparalleled, I believe, in all human history—were evidently adequate to such an effect, and the fact that immense quantities of something were thrown into the air is attested by the greenness of the sun as seen in India. Besides, the time since the Java earthquake has been just about what we might suppose sufficient for the dust to diffuse itself to this distance. Sixty-one tons of impalpable dust thrown into the air would allow one ounce to each tract of ten miles square over all the earth's surface. This, I think, would be quite sufficient when viewed at an oblique angle with the stratum containing it, and nearly in the direction of the sun, to be plainly visible. Having thus an adequate and probable cause, there seems to be no need of ascribing the phenomenon to any mysterious extramundane cause, of which we can know comparatively nothing, but of which we may imagine everything.

PHOTOGRAPHIC PROGRESS.—Photography is one of the miracles of modern times. The art has taken strides with seven league boots since the time of Daguerre, who made a picture on a metal plate, which had to be turned and twisted in every direction before you could find what you were looking after. Lately pictures have been taken with such rapidity that lightning is compelled to strike a faster gait to keep up with the process. Dr. Koch tells us that he has photographed with a photomicrographic camera that most minute filament, the flagellum of the bacteria. One might be satisfied with photographing the bacteria as a whole, since it is beyond the reach of naked vision; but to take a picture of an insignificant portion of it is like getting up among fairy tales. Mr. Rockwood, also, has succeeded in getting satisfactory pictures of the vibrating point in the diaphragm of a telephonic instrument while a person was speaking at it, and by means of a spark from Leyden jars. The work must have been done in the one twenty-four thousandth part of a second.

COMPENSATIVE HEAT EMPLOYED BY DIFFERENT LIGHTS.—The general knowledge that the electric light produces very little heat in proportion to its illuminating power has been reduced to figures by *Nature*, which gives the following result of careful experiments: The heat from an arc lamp of 100 candle-power is from 57 to 158 heat units, that of the incandescent lamp, of equal brilliancy, from 290 to 536. The Argand gas burner is the next best light in point of coolness, but this is represented by 4,860 heat units, a colza oil lamp by 6,800, a flat wick petroleum lamp by 7,200, a paraffine candle by 9,200, and a tallow candle by 9,700. Light for light, therefore, the heat of an electric arc lamp, under the most favorable circumstances, is to the heat of tallow candles as 1 to 170.

NATIONAL MUSEUM OF ENTOMOLOGY.—Prof. C. V. Riley, the entomologist of the Department of Agriculture, has deposited with the Smithsonian Institute his own private collection of insects, with the idea of using it as a nucleus for the development of a collection fitting the dignity of a national museum. The collection deposited comprises some 30,000 species and upward of 150,000 specimens of all orders. The most important addition to the Institute has been Mr. Ridgway's private collection of American birds, containing 2,302 specimens of 778 species, especially important because the specimens have been selected in field to illustrate variations of color and form due to age, sex and geographical location.

AGRICULTURAL VALUE OF ENTOMOLOGY.—For several years past the Swedish government employed an entomologist to assist the farmers in distinguishing and destroying insects that prove hurtful to the crops. The demand for his services has been so very great, and the work he has done has been so useful, that the office of Government Entomologist is to be made a permanent one.

SAND AND WATER.—Some of the conclusions of science would indeed be appalling but for their practical harmlessness. Thus geologists assert that if the continents and the bottom of the ocean were graded down to a uniform level the whole world would be covered with water a mile deep, so much greater is the depression of the ocean bed than the elevation of the existing land.

EXPERTS in chemistry have estimated that the cost of London's winter smoke and fog is \$25,000,000 annually; that is to say, constituents of coal to this value escape unconsumed, and assist in forming the sooty vapor.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ST. JULIAN.—*Sentinel*, Dec. 26: The excitement in the court house concerning the St. Julian quartz mine still continues. Except the payment of taxes business is practically suspended. Every one of the owners can be seen walking around with a piece of quartz in hand, which he tastes, washes, pounds, assays and dreams sweet dreams of countless wealth over. They have a ledge of very good looking rock about eighteen inches wide which if it continues will make the St. Julian a noted mine, and in truth justify the excited state of mind of its owners.

VOLCANO.—*Cor. of Dispatch*, Dec. 29: The Downs mill started this morning; they have struck very rich rock lately, and put more men to work. Gillick & Phillips are going to start up their mill this week. The rock from their mine is very rich, and continues to improve as they sink. All the mines at Pioneer are in operation. The Tunnel Co. will soon commence to wash.

NOTES.—*Ledger*, Dec. 29: The upper tunnel at the Mammoth claim is still 150 ft. from the shaft. An error in the calculations of the surveyor led to the impression that the work was 150 ft. nearer the desired spot than it actually was. It will require two months' work yet to reach the shaft. The Tailisman mill was expected to be started up in South Spring Hill rock yesterday. Jack Tregloan is in Amador, inspecting the mine, etc. More than 100 tons of rock have been hauled to the mill, and its paying character is conceded by all. It is not a pocket mine, but one apparently destined for a long career of gold production. At the St. Julian the owners took out about 800 ounces of rich metal early in the week, since which little has been done. At last accounts the ore body had widened to 3 ft.

MIDDLE BAR TUNNEL.—Thursday night, at the big tunnel at Middle Bar, something got loose about the machinery of the air compressor, resulting in one of the large fly-wheels being smashed to pieces. The wheel cannot be replaced inside of two weeks. This accident has brought one of the drills to a standstill. The other is in operation. The face of the tunnel is in a distance of over 400 ft.

Calaveras.

SAN ANDREAS.—*Citizen*, Jan. 5: Work has been resumed on the San Andreas Grave mine, and new pumping machinery will be placed in the mine to overcome the immense volume of water. It is said that a quartz vein was found in the level at a depth of 100 ft. from the surface, and though the rock has not been tested, it has the appearance of being good milling ore.

NOTES.—In addition to the Ora Plata mill, now in operation, Jim Morse's five stamp mill is running on ore from the screen of the hydraulic works of the Ora Plata Co. The ore is low grade, but free milling, and if the result in wet crushing proves as good as anticipated, a number of stamps more will be added. Col. Dorsey has mining interests across the river immediately opposite Collierville. It is said that he has bonded all the mines in that district for the sum of \$370,000. Jas. L. Sperry is working his iron mine in this immediate neighborhood. This mine at no distant day will become famous. The assays show 60 and 70 per cent iron.

ANGEL'S CAMP.—*Mountain Echo*, Dec. 26: Leper & Co. are still working the Invincible and it is paying well. The 40 stamp mill on the Reserve is kept steadily at work and is said to be paying well. The new mill on the Morgan mine will soon be completed and ready for operation. The ore body in the Porter mine is six ft wide and immensely rich. This will eventually be the leading silver mine on this coast.

El Dorado.

INDEPENDENCE MINE.—*Placerville Democrat*, Jan. 5: Some 16 or 17 years ago this mine was worked by Chas. McLane and Geo. W. Swan, who ran several tunnels and sunk a shaft to the depth of 50 feet. Much good milling ore was taken out, and a 12-stamp mill erected. About this time there was a misunderstanding between the owners, and work was suspended. Since then the mine has been idle, notwithstanding the ore taken out averaged about 16 per cent. Recently this mine was bonded to a company of Cleveland capitalists, who have put a force of men to work, and one of the old tunnels has been cleaned out for about 400 ft, and looks even better than was represented. Work is now being prosecuted on the shaft, which has already been cleaned to a depth of 20 ft.

GOOD NEWS FROM GRIZZLY.—There is no abatement in the "Grizzly Flat boom." All of the mines started up during the past year, with but one exception, are still working full forces of men, and, judging from the fact that these men get their money regularly after the monthly clean-up, gold in paying quantities is being found. The best news from this district is that a wealthy Eastern company has bonded the old Eagle mine, and will at once put a large force of men to work prospecting it. The Eagle is on the same lode with the old Mt. Pleasant and Eagle King, on String canyon, and in early days was very rich.

EUREKA.—*Georgetown Gazette*, Jan. 4: The Eureka mine is being pumped out, and next week active work will begin in the mine. The hoisting works and machinery have been very much improved, and everything is in tip-top shape. The reduction works will be completed in another week. No pains have been spared in making this one of the best put-up mills to be found in the State.

Mariposa.

MARIPOSA IMPROVEMENT CO.—*Herald*, Jan. 4: The clean-up made on the 24th, at the Yosemite mill, from 14 days run of 20 stamps on Mt. Gaines ore, resulted in a return of 34 lbs. 9 ozs., and, in gold, valued at \$5,700; also, gold in the battery sands and sulphurates estimated at \$1,500 more, or a total of \$9,000 for 14 days run of 20 stamps, at a cost, as returned to the Directors, of \$3,200. Had the full number—30 stamps—been in repair and running on the same ore, the result would have been \$13,500 for the two weeks, or a total of \$27,000 for a month's run. The Gaines mine is showing up

finely and a quantity of rich rock is being obtained, one piece of a few pounds weight yielding \$6.50.

A portion of the property of the Mariposa Improvement Co. consists of three claims on the Merced river, near the mouth of Cotton creek. In the progress of the assessment work at present being done on the claim, a fine ledge, four ft wide, of good ore, assaying \$28 per ton in gold, has been developed. This claim is so situated that for many years large quantities of the ore can be obtained without hoisting a pound or pumping water, as a tunnel will be run along the ledge, and will at once give an available supply of ore for a large plant.

Mono.

LUNDY.—*Bodie Free Press*, Jan. 6: The strike in the Clifton mine is one of great importance. The 3 strata of ore encountered 10 ft above have come together, forming 4 ft in thickness of solid quartz from all the drillings, and from any portion of which free gold can be readily obtained. Win. F. McKenzie and Pat Regan this week put a force of miners to work on the Mormon mine, a relocation of the Little Emma. The richest ore ever found in Homer district was taken from this mine—\$2,000 to the ton, or \$4 per pound, an average of a quantity crushed—one specimen the size of a walnut containing \$60 in gold. Mike Noonan has resumed work on his Hyena tunnel, in the western wall of Lake canyon. The Hyena is believed to be the southerly continuation of the Gorilla lode. Twenty-five to thirty men are still employed in taking ore from the May Lundy, and a number of mules are engaged in packing to the mill, which is kept running day and night. Ab. Bagby has resumed work for the winter on his tunnel, following the Grizzly lode into Mount Scowden, a short distance above the May Lundy mill.

BODIE BOOMING.—*Free Press*, Jan. 4: Wednesday morning W. H. Lent arrived in town, and that evening the stock closed at \$1.50. Yesterday it opened at \$2 in the morning streets, was \$2.25 on the morning board, jumped to \$4, and then to \$5.50 on the evening board, and closed at \$5.50 asked after the board. Reports of all kinds were flying around last night as to the cause of the raise. That which seemed to be most generally credited was, that while prospecting in the old workings at the 300 level, a vein of rich ore had been encountered, which had been followed for some distance and had pinched out; that afterwards it had come in again very rich, and in a way to suggest something like the old Bruce and Burgess bonanzas. This is entirely unofficial and unauthenticated. At all events, the stock quotations show that there is something unusual in the wind. There is considerable of the stock held in Bodie—probably 10,000 shares.

JORDAN.—S. O. Johnson the indefatigable prospector who has been at work in Jordan district for the past three years is in town again. He reports that the vein in the Levenfelt tunnel looks better every day, and that San Francisco parties have made him a cash offer for it. About half a dozen relocations were made in the district on New Year's morning.

STANDARD CON.—*Bodie Free Press*, Jan. 1: There were extracted and shipped to the mill 1,151 tons of ore; 2,085 ounces of crude bullion were received, and \$17,245 were shipped to the company. Upraise No. 1 from south drift No. 2, 1000 level, is up 180 ft showing five ft of vein, which looks well. Upraise No. 2 from same drift has been raised 18 ft; total height 101 ft. The vein is four and a half ft wide and looks well.

BODIE TUNNEL.—The ore in the north drift is fully three ft wide, showing a strong and well defined formation going north. The average sampling of the ore last week in the levels and upraises were \$19.50 per ton, although the 300 level and the upraise gave an average of over \$22 per ton.

BODIE CON.—During the week ending the 29th, there were 122,130 tons of ore hauled to the mill, and the same amount was crushed. The average assay value of the pulp was \$31.21; that of the tailings was \$4.72 per ton. The bullion shipment amounted to \$7,590.32.

Nevada.

GREYHOUND MINE.—*Grass Valley Union*, Jan. 8: The Greyhound mine on Deer creek, in the vicinity of the Imperial mine is said to be showing up handsomely at which the owners are feeling very much encouraged. The stock is all owned in Grass Valley, principally by working miners in the Idaho and Empire mines.

IDAHO.—A regular monthly dividend was declared by the Idaho Mining Co. yesterday of \$5 per share, amounting to \$15,500. The mine is producing well, and is in good shape, and the probability is that the present year will average well with the output of previous years.

DERBEE.—*Transcript*, Jan. 8: The first dividend of the Derbee Mining Co. will be paid at their office in San Francisco on Monday. It was contemplated to place the mine on a dividend paying basis last November, but owing to the improvements being made, and the laying in of the winter supplies, the commencement of dividends was postponed until now. The new tunnel being completed and all connections made, the expenses will be materially reduced. The mine is looking very fine, and the gravel that is being washed is of a most excellent quality. The stockholders have now a good prospect of getting their money back, besides having a substantial value to their stock in the future. The company have an immense body of ground that has never been worked, and there is no good reason why the Derbee should not be a regular dividend payer.

NEW YORK HILL.—*Tri-Weekly Herald*, Jan. 5: We learn that a rich streak of ore was struck in the 1300 level of the New York Hill mine, near Grass Valley, yesterday afternoon. The ledge is well defined and the rock taken out is of high grade, considerable free gold being seen in the quartz.

Placer.

BELMONT MILL BURNED.—*Argus*, Jan. 3: The mill and works of the Belmont mine, 3 or 3½ miles below Ophir, were burned to the ground on Tuesday night. The fire was undoubtedly the work of an incendiary, for the mine had been shut down for several months past. It was a 10 stamp mill, one of the largest and best constructed in the State. Mortar blocks had also been laid for the erection of another 10 stamp mill. It was well equipped, and must have cost from \$30,000 to \$40,000. Two watchmen were constantly employed to look after

the property—a Chinaman and a young white man named Charles Thompson.

ALTA.—A dispatch from Alta to the Sacramento *Bee* of the 31st ult. says: "The Alta mining shaft at this place is doing nicely, and it is expected that bedrock will be reached in a few days, when drifting will begin and give employment to a number of miners. Three shifts are working, and the shaft is down 180 ft. The gravel prospects well. A teaspoonful of gold was the result of one pan. Otis Atkinson and a few other Virginia City gentlemen are interested in the claim. There are not any shares for sale.

SUPERIOR IRON FROM PLACER COUNTY.—The *Oakland Tribune* says: The California Iron and Steel Co. find that the iron from the Clipper Gap mine, in Placer county, is of so superior quality that malleable castings can be made from it. As a test, castings have been taken from the annealing furnace bent entirely out of shape without showing a break, then heated and drawn out and the two ends welded. Castings in the shape of rings have been hammered into straight pieces, the material showing more of the qualities of wrought iron than of a casting.

Plumas.

CONKING LEDGE.—*Quincy National*, Dec. 29: During the past two years, Mr. D. L. Haun has been engaged in running a tunnel at Argentine to tap a quartz ledge, known among the old miners there as the Conking ledge. The rock proved very hard, and it has taken a long siege to get in, but a short time ago the ledge was reached, and proved very encouraging, as the rock prospects splendidly, and much of it shows free gold. But little development has yet been made, the tunnel only having been driven into it two ft, but Mr. Haun is sanguine that he has opened a valuable mine.

OPHIR CON.—*Greenville Bulletin*, Jan. 2: Fine prospects have just been found in the Ophir Con. Several years ago Mr. Sherman found some very rich rock on the mountain side, just above the old Crown Point. He prospected the place but little and after having failed to induce parties to help in running a tunnel to prospect the ground, he gave it up. Last summer as Mr. J. P. Hall was coming down the mountain, at a short distance from his Primrose ledge, he came across the place Mr. Sherman had abandoned. While carefully examining the ground he picked up several pieces of rock that showed gold freely. Mr. Hall at once started a tunnel, a contract being let which was lately completed. A cross-cut was started, and at a distance of 23 ft the ledge was struck. The first piece of rock taken from the ledge showed several colors of gold. The rock is of a snuff color, and by all is said to be the finest seen in the town for many a day.

NOTES.—A little to the south and east of the Ophir Con, the McIntyre Bros. and D. McIntosh are running a tunnel to strike the rich chimney worked many years ago by H. C. Bidwell. Work will soon be resumed on the Wild Cat, which adjoins the Ophir Con, on the west. Green mountain stock is rising in price at the New York Mining Exchange. It is worth 50 per cent more than it sold for less than six months ago. Barney Tutt has been running an astrak in Genesee valley for some weeks past. A clean up was made some days ago, and the rock was found to average \$15 per ton.

San Bernardino.

BIG BULLION SHIPMENT.—*Index*, Jan. 5: Today Hues Thomas and John C. King arrived from Oro Grande with 18 immense bars of bullion, amounting to \$31,570—the result of only 14 days' run on ore from the Silver King of Calico. This immense deposit of silver bullion can be seen at the Express office. It is the largest shipment of bullion ever made from Southern California, and coming as it does from 14 days run shows the extraordinary richness of the mines of San Bernardino county. Mr. Thomas says there is enough ore at Oro Grande to run the mill about 40 days longer, when all ore will be milled at the Oriental, Calico. Mr. Thomas showed us a specimen of ore from the 600 level that exceeds anything ever taken from the mine.

CALICO NOTES.—*Print*, Jan. 5: The Garfield has a large quantity of ore on the dump waiting shipment besides the regular amount mined and shipped every day. The Garfield and Gobbler are working large forces of men, and the numerous buildings near the mines indicate a new town independent of Calico. Ore taken from two new locations lately made in Snow Bird canyon assays 440 ounces. These claims, the Richmond and Lookout, are owned by Messrs. Taggart, Keys, Sinclair and McGlinchy. The Cuba No. 1 has just started up again. We were shown some very fine ore. The Cuba has large bodies of ore and will make a shipment to Colorado in a few days of about five tons. The Sam Houston No. 3 has been lately purchased by Messrs. Kauffman and Hart, and a large force of men are taking out ore for shipment. The Blackfoot mine is also working, and has a large body of ore ready for shipment. Mr. Geo. L. Bailey has re-leased the Kearsage mine and will ship 20 tons of ore to Colorado in a few days. Mr. Bailey informs us the Kearsage is the "boss" mine, and he is making big money for himself and the owners. The Bismarck owners are having a new road built which will greatly facilitate the transportation of their ore.

hasta.

FRENCH GULCH.—*Cor. of Redding Independent*, Jan. 4: The Niagara Mine Co. got their mill (cannon ball), 12 tons in 24 hours capacity on their claim, with the arrival of the "beautiful snow," which will soon be in running rig, storm or not. And these mills seem destined to revolutionize quartz mining.

OLD DIGGINGS.—The *Democrat*, says: Dan O'Neal's cannon ball mine is running on his old claim in the Old Diggings district near Buckeye. The rock in this claim is very rich and Dan expects to accumulate wealth fast. The Mammoth mine, an extension, is showing up some of the richest quartz ever found in the county. Leaf gold was found in this ledge last week.

Sierra.

GOLD BLUFF.—*Downville Messenger*, Jan. 5: The lower tunnel now being run on the Gold Bluff quartz ledge is in over a hundred ft, and is being run as rapidly as two shifts can push it. This tunnel will go in 1,200 ft before it reaches the ledge, and will strike it at a depth of 250 ft below the upper levels.

DEIDESHEIMER.—The survey of the recently located quartz ledges of Deidesheimer, Sunderhaus, Busch and Hughes, near Sierra City, has been com-

pleted by C. W. Hendel, inclusive of a mill-site and water right. A tunnel will be soon started for the pay chimney, and in the spring a 10 stamp mill put up, and a road made to the mine.

SIERRA CITY.—*Cor. Downville Messenger*, Dec. 29: There are over a hundred men employed at the Colombo, and 10 stamps started before Christmas. Everything in the shape of buildings, machinery, etc., needed in the working of an extensive quartz mine, has been provided, and naught remains but to crush the ore and ship the bullion to the mint. The Marguerite is paying steadily, and has a large number of men in their employ. The new mill of the Sierra Buttes Co., at the lower end of the city, is rapidly approaching completion. Sierra City bids fair ere long to become a second Virginia.

RUBY.—*Tribune*, Jan. 3: Fifty-two and three-quarters ounces of gold were cleaned up at the Ruby mine last Sunday, as the result of washing 350 car-loads of gravel, taken principally from the main tunnel. A 15 ounce nugget was included in the clean up. The main tunnel has already been driven 260 ft across the lead without encountering any signs of the east rim rock. Two new breasts will be opened out next week, making five in all. A few new hands have been put at work, but the scarcity of water prevents any large increase of the working force at present. There are two ft of snow at the works.

Siskiyou.

ORO FINO ITEMS.—*Cor. Yreka Union*, Dec. 27: Maurice Lewis, Burk & Co. are opening up the quartz lead known as the Bratt lead, with a force of five men. The lead is situated on the west side of the Oro Fino mountain, and due west of Oro Fino. The ledge is from 12 to 15 inches thick, and prospects remarkably well. Mr. Gilmore & Son of Hall gulch are down on their lead 150 ft, and the lower tunnel is in 250 ft. The ledge is about 10 inches thick, and prospects very well. Mr. Gilmore is an expert miner. The Lindsey boys and others have struck some very rich quartz somewhere on the Oro Fino mountain, but I have not learned exactly where.

Tuolumne.

WILLETTA.—*Sonora Independent*, Jan. 5: Bill Long has a 20 stamp mill ready to put up on his Willetta mine, which is about half a mile east of Jacksonville on the mother vein. One hundred tons crushed some time ago went \$11 per ton. The average width of the vein is from 50 to 75 ft of decomposed quartz, and averages from \$5 to \$8 per ton. The vein is from 200 to 300 ft high and can be quarried like a gravel bank. The material can be mined and milled for less than \$1.50 per ton, and can be milled for less than 50 cents per ton. The main Tuolumne river flows at the base of the mine, which is capable of furnishing an unlimited supply for any number of stamps desired for the year round.

NEVADA.

Washoe District.

ALTA.—*Enterprise*, Jan. 5: The whole line of pumps has now been enlarged and all are working smoothly. Men have been put to work at repairing the west drift. The east drift on the 2150 is found to be in good order, but in the west drift there are places where there are small caves and where it will be necessary to put in a few timbers.

GOULD AND CURRY.—The usual progress is being made in sinking the joint Best and Belcher winze below the 2500 level. The ground at the bottom is still soft, and some water is coming in.

SIERRA NEVADA.—Good headway is being made in the upraise from the 2900 level. The northeast drift on the 3100 level is still following the quartz streaks lying in that direction.

CROWN POINT.—Some ore is being taken out, but they are not yet able to put on a full force of men, as the mills on the Carson river can reduce but a limited amount of ore.

YELLOW JACKET.—A considerable amount of ore is being extracted, but owing to the low stage of water in the Carson river a full force of miners cannot yet be put to work.

UNION CON.—Good headway is being made in the main south drift on the 3100 level. The ground is still in vein porphyry of the usual character.

BEST AND BELCHER.—Good headway is being made in sinking the joint Gould and Curry winze below the 2500 level. The material encountered is of favorable appearance.

UTAH.—Good progress is making in the new northeast drift on the 1750 level. The ground works well.

IMPERIAL.—The main west drift is now within a short distance of the old upper levels, which it is intended to explore and overhaul for ore.

SCORPION.—The usual progress is being made in main west drift on the 500 level. There is no change of formation worthy of note.

COMBINATION SHAFT.—The new hydraulic pump at the 2600 level has been started up, and is found to work well and smoothly.

CALIFORNIA.—Fair progress is making in the joint Con. Virginia winze now being sunk below the 2700 level.

HALE AND NORCROSS.—The water has been pumped out of the winze below the 2700 level, and work at that point resumed.

OPHIR.—Some ore is still being extracted on the 150 level, and a winze is being sunk to the levels below.

CON. VIRGINIA.—The usual progress is being made in sinking the joint California below the 2700 level.

MEXICAN.—Are timbering up the main north drift on the 3100 level and putting in drain boxes.

UNION SHAFT.—The work of easing timbers and repairing is still continued at the 2300 station.

ANDES.—Some low grade ore is being extracted, and prospecting continues at several points.

OVERMAN.—A small amount of ore is being taken out of the old upper levels.

BELCHER.—Some ore is still being extracted from the old upper levels.

Belmont District.

BELMONT MINE.—*Courier*, Dec. 20: The Belmont M. Company's mill will soon shut down, and will remain closed during the winter. It is the intention of the company to enlarge the leaching works,

as the present run has demonstrated that there are not enough leaching tanks to keep the mill running constantly. Enough is known of the leaching process, however, to justify the assertion that it is a success here.

SUPT. N. C. Bissett informs us that work will be prosecuted with energy in the Belmont mine this winter.

OFFICIAL.—The following is a copy of Supt's letter of December 29: The ledge in north stope from 200 level is considerably out of place, but showing large bodies of quartz and some ore. All other stopes from this level as well as stopes in South Tunnel looking well and yielding the usual amount of ore.

NOTES.—Very rich chloride ore has been struck in Green Aldrich's mine, the Seventy-seven. The mine owned by Messrs. Bartell, Hall and Colligan continues to look well. The Tybo mill will close down on Monday next.

Candelaria District.

COLUMBUS CON.—*True Fissure*, Jan. 5: The main shaft has attained a depth of 25 ft below the station on the third level. The ground is now more compact than heretofore and showing streaks of mineral matter, the most of which is quartz of a promising character. The work of sinking the shaft will be continued until it has reached a sufficient depth for cutting out stations for the fourth and fifth levels. The drift from the shaft on the third level has reached a length of about 20 ft. The slow progress is owing to the ground in the drift being very hard.

MOUNT DIABLO.—There are no new developments to report from the mine for the past week. Work was stopped on the night of December 31st, and the mine closed down temporarily for the purpose of making repairs to the engine and putting in a new foundation for the same. The engine was sent to Carson City to the shops of the Virginia and Truckee railroad company on January 3d. It will be several weeks before everything is in shape to start work again, and meanwhile there are but a few men working on the foundation and on the surface of several of the claims. The ore on hand at Belleville has been milled and the mill will be cleaned up as soon as possible. A shipment of bullion amounting to \$6,537.28 was made December 31st.

SODA SPRINGS.—An air of hopefulness is prevalent at Soda Springs. It is reported from authentic sources that it is exceedingly likely that arrangements will be made to immediately start the copper furnace at Soda Springs. This will be agreeable news for the owners of copper mines.

Eureka District.

FARROW MINE.—*Sentinel*, Dec. 30: George Story, with another miner, is doing some good development work on Farrow mine, situated on South Alhambra Hill. The main shaft was sunk on heavy iron croppings, and in this the assessment work was done for this year, when a small streak of ore assaying \$114 per ton, silver, was encountered. A tunnel was formerly started from a point below the cropping to cut the lode. It is now in 75 ft, and the prospect for a paying body of ore is very good.

PHOENIX.—The tributors in the Phoenix were rushing around yesterday to ship 20 tons of ore before Jan. 1st, in order to save \$5 per ton in the rates of reduction raised after that date.

NOTES.—Good reports continue to come in from the Enterprise mine at Diamond. The company is making money right along. Tributors in the Bald Eagle are working in strictly virgin ground, with good prospects of finding themselves "in bonanza." Parties are talking about leasing the Matamoros furnace to reduce custom ores. There is also some talk of putting up a sampling mill. Considerable quartz and iron is coming in, in the workings of the Golden Rule Tunnel. The prospects there were never so good as now. A new drift will be run from the shaft in the Silver Connor mine to tap the ore body below the present stope. The mine is panning out well. Assessment work is being completed on the Pioneer, the Red Bird Company's mines, the Eagle Series and other mines in that locality of Goodwin canyon. Messrs. Hilkey and Yerrick are developing the Nahant mine, on the eastern base of Silverado Mountain, by means of a new tunnel, now in 20 ft. There is good pay ore on the surface, about 100 ft above the tunnel, which it is their aim to prospect. A connection has been made between the second level of the Eureka Tunnel and the incline winze from the first level. The facility for prospecting the mine between the two points is good. The force of men employed is small, but the mine is paying its way. Advance capital is what is needed to do the dead work.

Paradise District.

RELOCATING CLAIMS.—*Silver State*, Jan. 4: According to reports from various parts of the county, a revival of the mining industry is setting in. In almost every district more or less claims were relocated on New Year's morning, and in Paradise and Willow creek everything that was subject to relocation was taken up, as the general belief is that there will be some excitement in these districts next spring. At Unionville, which has been under a cloud since the Arizona mine was shut down, the relocators were busy, as miners have not lost faith in the camp. Several claims were also relocated on Winnemucca mountains, and in Gold Run district, east of Golconda, very many were taken up.

Ptoche District.

DON'T WANT TO SELL.—*Record*, Dec. 29: The owners of the Raymond & Ely property, who stated that they were anxious to sell it, were offered the price they said they would take, when they at once raised in their price some \$20,000. The Meadow Valley Co. were offered the price they said they would be glad to sell for, when they raised the price of their property also. The owners of these properties, the way it looks to the public, have no idea of selling them.

EL DORADO CANYON.—The mill at El Dorado canyon, leased by Cronin, was to have started up on last Monday. Mining matters at the canyon are prosperously moving along. The mill of the Southwestern Company continues turning out the silver bars at a lively rate.

ASSESSMENT WORK.—The claim-owners in this whole vicinity are now putting in big ticks doing assessment work. They do not want to take chances on relocating. There are too many people on the alert and watching chances to take up claims.

Reveille District.

MANHATTAN.—Alf Doten writes from Austin to

the Virginia *Enterprise*, of Jan. 6: The old Manhattan mill has just started on a fresh run, after a couple of weeks' rest for repairs and a thorough clean-up. A gratifying peculiarity with this institution is that its bullion yield is continuous, the regular shipment of bricks being made every other day, or oftener, whether the mill runs or not. In fact some of the heaviest shipments have been made since the mill shut down. A thorough clean-up of this mill literally means something. Crushing the ore by Stedefeldt dry process involves the gradual accumulation of light, rich chloride dust everywhere, as well as in the regular dust chambers and other traps. The whole concern has to be scraped and swept from one end to the other, and the pans are thus kept working long after the batteries have ceased their noisy racket. Just what bricks have been turned out in the way of bullion shipments during these two weeks that the mill has shut down, would make any newspaper man feel rich.

Tuscarora District.

BELL ISLE.—*Time-Review*, Jan. 3: The north drift on 450 level has been advanced 10 ft during the week, showing no change worthy of mention.

NORTH BELL ISLE.—Work is progressing in and about the mine as usual, and the usual amount of ore being extracted.

ARGENTA.—South crosscut in 38 ft, progress for the week 8 ft. Ground is more favorable, and have cut a small stringer of low grade ore.

ARIZONA.

TONTO BASIN.—*Prescott Courier*, Dec. 31: The section of Yavapai county known as Tonto Basin, is east of the Verde river and north of Salt river. Samuel Hill recently induced Charles Ryall to visit his mine, the Zula. Mr. R. found the mine opened by shaft, to a depth of 75 ft, at the bottom of which he saw a nine ft vein of quartz, carrying, per ton, in gold, \$75. Two hundred tons of such are on the dump. The ore is free milling. Mr. Hill tells us that he will keep men sinking on the lode and that, as the ore body is constantly enlarging with depth, he has reasons for believing that it will yet be 15 or 20 ft wide.

ROSS CAMP.—*Prescott Courier*, of Dec. 28: R. W. C. Merrington is preparing to work concentrators in connection with stamps at the Senator mill. He has ten stamps and plenty of mill room, but at present only intends running five stamps, with two Frue concentrators. Mr. Merrington has on hand lots of ore from several different mines near by, from 10 to 25 tons each. There are fifty mining claims within five or six miles of the mill, carrying gold and silver in connection with base metals and ranging, in assay value, from \$25 to \$75 per ton, which can be concentrated from five to ten tons into one, when the product will bear shipment to reduction works at Argo or Pueblo.

SUNSET MINE.—Rich horn silver has been struck in the Sunset mine in the Weaver mountains. The mine is owned by Secretary Van Arman, and the developments now being made on it are demonstrating the fact that the genial Secretary has "caught on" to a bonanza.

HOWELLS.—The five stamp mill at Howells is all the time going. It and the Cornish rolls have reduced as high as 22 tons of ore in 24 hours. Two concentrators are not sufficient to take care of the pulverized stuff and a third one will soon be put up.

SILVER BELT MINE.—*Cor.* of *Prescott Courier*, Dec. 31: Everything is much better than we anticipated. We are taking out plenty of ore, have two carloads ready for teams. The south stopes are on a bonanza, have black sulphurets in the south level, will start two shafts on it to-morrow.

THE RUCKER MINE SOLD.—*Epitaph*, Dec. 22: Among the papers filed for record yesterday, were deeds from G. E. Hinnet, T. D. Byrne and John Dunn, conveying to Ben Williams, of the Copper Queen, the Rucker mine of Bisbee. The Rucker was the first location made in Warren district. The claim is in reality an eastern extension of the Copper Queen, but a few ft intervening between the two claims. Forty-one thousand dollars is said to have been paid for the claim, of which Messrs. Dunn and Byrne, who owned five-sixths, received \$20,000 each, and Hunter \$1,000 for the remaining sixth.

HARMONICA.—*Mohave Miner*, Dec. 30: Jack Stoen, Mike Farrell and Tom Burke are putting in their best licks on the Harmonica mine in Gold Basin district. The development consists of an 80 ft shaft and a drift 40 ft long. Work is carried on in the main shaft and the ore continues to improve as depth is attained. The ledge has been crosscut some 17 or 18 ft but its full width has not yet been determined. Ore from the mine will carry from \$20 to \$80 per ton in free gold.

YUMA COUNTY.—*Arizona Sentinel*, Dec. 22: An important discovery of gold placers has been made in this county. Don Marcelino, an old resident of Yuma, is the discoverer. The diggings are back of the Castle Dome Range, 50 miles from Castle Dome Ldg, and 80 miles southeast of Ehrenberg. The placers are ten miles from water and are being worked with dry washers. The pay dirt is from four to five ft thick, and the most gold is found in the gulches. The discovery was not generally known here until a few days since, as most of the trading was done in Ehrenberg. The heavy rainfall of late has compelled a cessation of work, for the time being. So far some three thousand dollars has been taken out and that in a very short time. This discovery is of great importance to Yuma county, and along with the steam dry washers now being worked at the old La Paz diggings will add greatly to the product of gold from this section.

OLD PAT.—*Pinal Drill*, Dec. 29: The Old Pat mine is situated three miles north of us in the high hills sloping towards Happy Camp. It is, to be sure, still a prospect, but one that shows several tons of very rich ore on the dump. As the work progresses they are following the mineral.

QUIJOTOA MINES.—*Virginia Enterprise*, Jan. 2: The Tucson *Star* of December 21st says: From William A. Scott, who has just returned from the Quijotoa mining camp, our reporter has obtained some points of interest. At the town of Logan, which is at the base of the Quijotoa mountains and near the Flood-Mackay bonanzas, there are now about 100 people, but the place is filling up so rapidly that each day makes a vast difference in the population. The permanence of Logan depends more or less upon the result of boring for water. I think,

however that Logan will be the permanent town, and that all the water needed for mills and other purposes will be found in the well now being bored. That will settle the townsfolk question. "The mines are the biggest I ever saw. I tell you, you have no idea, if you have never been there, of their extent and richness. I had no idea, until I went there, of the value of these Quijotoa mines. They are simply immense." Mr. Scott says the road between this city and the great camp is alive with people going to the bonanzas—some in wagons, some on horseback, others in stages, and some even walking and carrying their blankets on their backs. He also met long trains of wagons loaded with lumber and goods of all descriptions.

CONTINGENT.—*Sahar Belt*, Dec. 29: The sale of the Peerless group of mines, in the Quijotoa district, recently bought for by Messrs. Mackay and Flood, is contingent on their finding water within 1,500 ft, of which there is not a reasonable doubt. Water, wherever sunk for in that section of country, has been invariably found at a depth of not exceeding 125 ft.

STAY AT HOME.—*Epitaph*, Dec. 30: Mr. Archie Nevins, a well known mining man, dropped into the city yesterday from the Quijotoas, and from him was gathered a few items concerning the new bonanza. About 20 men will be the number employed when the mines first start up. There are now in camp fully three times as many practical miners as will be needed for some time, and Mr. Nevins advises parties looking for work to wait at least four months. Water has to be hauled about six miles at present, although the bonanza firm are busily engaged in sinking a well at Logan City and intend going to a depth of a 1,000 ft if necessary before abandoning the attempt to find water.

IDAHO.

ELKHORN.—*Ketchum Keystone*, Dec. 26: Col. I. Lewis states that the Wood River country is booming. The town of Ketchum, near which the Elkhorn is situated, is now a lively little city of 1,000 inhabitants. A branch of the Oregon Short Line is at Hailey, within 12 miles of Ketchum, and will reach it in the spring. There are 4 water jacket smelters at Ketchum, running upon custom work, and erected at an expense of \$250,000. What is known as the Wood River region is a belt of country 80 miles in length, commencing at the Sawtooth mountains and extending southward on each side of Wood river 20 miles. In this region not less than 5,000 mines, principally silver, have been located in the past three years, and of these at least 150 are now yielding princely revenues.

PARKER VEIN.—*Ketchum Keystone*, Dec. 29: On Christmas eve the men driving the tunnel to tap the Parker vein at the depth of 100 ft, struck ore, and not till they had driven 5 ft further was the opposite wall of the ledge struck. In driving across the vein four tons of high grade ore was extracted, consisting of auriferous copper, carbonates and galena. Three tons of ore worked as a sample, yielded 587½ ounces in silver per ton, and assays running as high as 2,865 ounces have been made. The mine is on Elkhorn Hill, about one-fourth of a mile above the famous Elkhorn, and is owned by Geo. Montgomery, Eugene Gillenwater, E. H. Terry, W. H. Watt and Sam Allen.

PRIDE OF IDAHO.—Dave Teachnor & Co. have completed the dead work on the Pride of Idaho, on East Fork, nine miles from Ketchum, and are now ready to go to sinking. A small batch of ore from this mine was sold to the Philadelphia Co. last summer for a little over \$200 per ton. They will, in a few days, commence extracting ore for shipment in the spring.

BANNER.—*World*, Dec. 25: Jess Bradford, who has a contract from the Elmira Co. for running 200 ft east on the Wolverine mine, Banner district, has lengthened the drift to 108 ft, besides crosscutting 38 ft. The ledge is 37 ft between walls. A vein, four inches thick has been struck on the hanging wall. The highest assay was \$136. This drift commences at the face of the main tunnel, 800 ft in length, and at the depth of 300 ft. Austin and Gallagher, who have a contract for running 200 ft west on the Crown Point from the same place, drifted 24 ft, then made a crosscut north, 45½ ft to the hanging wall. The first 2½ ft were through ledge formation with iron oxidized; then through decomposed quartz 23 ft, where the ore forms. The ore seams are from 4 inches to 14 inches thick of high grade ore. From all appearances they are on the extreme east end of the ore chimney. Everything looks favorable for a bonanza.

KETCHUM.—*Statesman*, Dec. 25: Mr. Joseph Pinkham arrived here last evening from Ketchum. He reports things in the most flourishing condition. The Philadelphia smelter is in full blast. The output of the Elkhorn for ten months of the present season was 400,050 ounces of silver, valued at about \$1.12 per ounce, making a total value of about \$450,000. This mine could have been bought a year ago for \$30,000. Now it would be difficult to guess at what figures it could be held.

COEUR D'ALENE.—*Elko Free Press*, Dec. 28: The Eureka *Leader* says: Mr. J. G. Parker, who is at Eagle City, Coeur d'Alene, has written a letter here to his wife, from which we are permitted to make the following extracts: "This place has exceeded my expectations. There is a better show for a great camp here than at any other place I have ever seen. It cannot fail. If only one out of ten of the many claims located turns out good there will be from 1,000 to 3,000 miners at work here in a year. Besides the 40 miles of placer ground already located, there have been some very rich quartz strikes made. This is surely going to be a great camp, for even now there are 100 men cutting logs and moving them to their lots, where buildings are being erected. There are three times as many houses here as when I arrived, and notwithstanding the dangers and difficulties incident to a trip, every day brings several new faces. Several have let contracts for the building of houses, and then hastened away for fear of being kept in here for the winter, on account of the trails being covered with snow. I have got in here in good shape; have a central location and the only hewn log house in town and the second one with a board floor. This by the way, is a luxury, as lumber rapidly sells for \$150 a thousand feet."

MR. J. C. BAKER.—*Inter-Mountain*, Dec. 29: It is the opinion of Mr. J. C. Baker, who recently returned from the Coeur d'Alenes, that if gold be dis-

covered on bed rock in Pritchard's gulch, the greatest mining stampede ever known will be the result next spring. The drain of Roubidoux & Co. has attained a vertical depth of 9 ft and bed rock is likely soon to be reached. About 300 men are in the diggings and many more are going in and coming out daily. There are no provisions there for sale and the stamperders can stay there only while the grub which they take in lasts. There is a small restaurant there which can only feed a few people.

ANOTHER.—*Virginia Enterprise*, Jan. 1: J. E. Stevens, formerly foreman of the Chollar mine, writes as follows from the new northern placers: I have been in camp five days. We have now four ft of snow, and the weather is extremely cold. Mining operations are suspended for the winter. I think this is going to be a good camp. The placers are very extensive, and there are some good quartz claims. Of course there can be no further prospecting done until the snow goes off, when this will undoubtedly become one of the liveliest camps in the country. It is believed that 20,000 people will come here in the spring. About 250 men will winter here. Provisions and all kinds of supplies are scarce and costly. It is difficult to get in here now, but will be much more so in the spring when the rush begins.

MONTANA.

CABLE MOUNTAIN.—*Butte Miner*, Dec. 29: The Cable mine is probably the richest gold producing mine in America. The property is closely held and the actual output cannot be definitely stated, but it is estimated that not less than \$10,000,000 has been taken out during the past four years. The mine at a depth of 140 ft shows a ledge 80 ft wide, which has been uncovered to the 400 level and from which pieces of quartz are taken carrying so large a percentage of free gold as to make them practically nuggets of metal. Last summer two tons of white quartz from this ledge yielded \$80,000 in gold, and it is not uncommon for a single blast to knock down from \$1,000 to \$2,000 worth of these nuggets. The mine is provided with a 20 stamp mill and employs 80 men in the mine and mill.

PYRENEES.—This also is a gold property, operated successfully by Salton Cameron, who formerly owned the Cable mine. The Pyrenees, 240 rods west from the Cable line, is developed by four tunnels which tap the ledge at a horizontal depth of 20, 50, 100 and 350 ft respectively, and a drift which has been driven on the ledge 800 ft east and west. The ledge is a true fissure vein from 6 to 12 ft wide, with well-defined foot and hanging walls, and carries a streak of decomposed, iron-stained quartz varying from 1½ to 10 ft in width. It is understood that a 20 stamp mill will be erected on the property next spring.

MARIA.—One of the most promising prospects in the district is the Maria, immediately north of the Alice and southeast from the Wabash mine. The property is owned by the Le Mout brothers. The lessees have erected a steam hoist and are prosecuting the work of exploration. The shaft has attained a depth of 120 ft. At the 70 level a west drift was run, from the stopes of which 91½ tons of ore has been milled which yielded a return of 105 ounces of silver to the ton. Three veins of considerable value have been developed by open cuts, and a station is now being cut at the 120, from which crosscutting will be commenced immediately to tap the ledge developed above in the 70 level.

MOUTON MINE.—Reports of strikes in the Mouton and Bell mines created a flutter of excitement early in the week. In the case of the Mouton, the mine is looking well, and the developments in the 400 foot southwest drift are satisfactory, but the managers regard the ore body uncovered as merely in the course of ordinary development, it having been not yet sufficiently explored. A winze has been started on the ledge from the 400 level, with a view to forming a connection with a drift to be run from the 500, but the winze is now in water, and sinking has been temporarily suspended.

BELL.—In the Bell mine, the discovery of a valuable ore body in the northwest drift is exceedingly satisfactory. The ledge is believed to be a continuation of that in the 240 level of the old workings. The ledge is from 6 to 8 ft wide, and carries a 2 ft streak of ore assaying 50 per cent of copper and 60 ounces silver. The extent of the ledge has not yet been determined, but the indications are that it is sufficiently extensive to supply the smelter with ore for a long time to come.

NOTES.—At the Montana Copper Co's Colusa the work of exploration is actively progressing in the 400, where a large body of low grade has been developed. The Alice properties are looking well and the usual amount of ore is being extracted. An extensive body of high grade ore has been uncovered in the 300 east of the Magna Charta. The Lexington product for 1883 will be nearly a million and a quarter of dollars. Clark's Colusa continues to look well. The north drift from the 210 foot station is now in a fine body of ore. The Pollack tunnel is still in good ore and the Clark brothers are making a good thing out of their lease. Clark's Fraction is worked on the 300 level through the Alice shaft and 5 or 6 tons of high grade ore is raised daily. The Amazon mine, at the mouth of Horse canyon, is likely to be worked by California parties, who it is understood are negotiating for its purchase.

NEW MEXICO.

STEEPLE ROCK.—*Cor.* of *Silver City Enterprise*, Dec. 28: The Nugget is running smoothly, taking out an abundance of good ore all the time. The Great Eastern, which is the east extension of the Nugget, and owned by Kistler and Currie, is looking well and bids fair to rival the Nugget mine. Assessment work is all that is being done at present. Work has been temporarily suspended on the Little Emily, having a four ft vein of rich ore at the bottom of the shaft. The owners of the Turk have finished assessment work and will resume after the first of January. The Eagle has had 125 ft of sinking done upon it in the last month by contract. The Jersey Lily, owned by Livingstone & Stowell, will have 100 ft of work done upon it after the first of January. The Ophir, owned by Barton, McDonald and Guthrie, is showing up big every day. The Carlisle mine is now running under the new management and many of the old timers are still retained by Mr. James.

For Mining Shareholders' Directory, Stock Reports, etc., see page 29.

Platinum.

American Occurrences.

Platinum, either comparatively pure, but more commonly alloyed to a considerable extent with iridium, osmium, or other metals of the same group, is found in small quantities in many of the gold placer regions of the Far West and Pacific coast, notably in California; and also occurs associated with placer gold in Virginia, North Carolina, Georgia, and other Southern States. A nugget of platinum found near Plattsburgh, New York, weighing 104.4 grains, is described in the *American Journal of Science*, III., xxi., p. 123, 1881.

Platinum usually appears in the form of small rounded and flattened grains. The occurrence of platinum in the United States thus far has been a matter of scientific interest rather than of any economic importance. Small quantities have from time to time been saved from the sluices of hydraulic mines, but were merely kept as a matter of curiosity. In 1877, 1878, and 1879, an irregular search was made for it in view of the then existing and prospective demand for the metal for incandescent electric lighting, and samples were obtained from many points, but many of the localities reported in the Southern States, as well as elsewhere, failed to afford specimens when specifically tested. No platinum in place, that is as ore in a lode, has at yet been discovered; its occurrence being confined, as above stated, to the placer deposits. A vein of platinum is reported to have been recently discovered near Hailey, in the Wood River country, Idaho, and small shipments of the ore have been made to the smelting works at Omaha. Although this find is called a vein, in the absence of definite particulars it is reasonable to assume that the metal is found in the usual form of stream platinum.

It is quite probable that in the future the production of platinum in the United States may become a regular industry; though from the indications which have been observed it does not appear likely that it will ever reach any very considerable importance. The quantity of American platinum marketed in 1882 was about 200 troy ounces. There are no regular quotations for the domestic metal. One manufacturer reports that the crude, unrefined American platinum which he has handled ran as low as .520 in fineness, as against .850 for the average crude Russian.

The method of mining is analogous to that of placer gold, with the exception that the apparatus for saving platinum depends upon gravity alone, and not upon gravity and amalgamation. The plant required for manufacturing platinum is simple and inexpensive, and the art has been developed to a high extent in this country. The best crucibles, etc., are made by hammering plate of the greatest possible density into shape. It is said that the cheaper spinning process which is sometimes employed has the effect of opening the texture of the metal and rendering utensils so made short-lived and unsatisfactory.

Imports.

The supplies of platinum consumed in the United States are derived from the Ural mines, where it is found in placers. The Russian platinum, however, mostly comes through French, English, and German laboratories, where the native grains are worked into merchantable metal. During the fiscal year ending June 30, 1882, unmanufactured platinum (wire or rod and sheet or plate) to the value of \$304,290, and manufactured platinum (consisting of three or four large stills for rectification of sulphuric acid) worth \$32,260 were imported, and during the same period manufactured platinum articles (consisting mainly of used-up stills sent to Europe for repair, or of scrap-metal) were imported to the value of \$19,244. Very little native Russian grain platinum is imported. The price of Russian unmanufactured platinum in New York at the close of 1885 was \$6 per troy ounce. The terms "manufactured" and "unmanufactured" are used in accordance with an old ruling of the Treasury Department drawing the line between dutiable and free entries. "Vases, retorts, and other apparatus, vessels, and parts thereof, for chemical uses," are now on the free list.—*Williams' Mineral Resources*.

The Signal Service.

The officers in charge of the various signal service stations on this coast have done all in their power to render the service of value to the people of this coast. They have shown much interest and industry in making known the results of their observations, and have shown a praiseworthy disposition to discover the peculiar conditions prevailing here, and to give the best deductions they can from their studies for the information of the public. But except in a general way they have not been able to do very much in forecasting weather because they have not sufficient data or means for obtaining it. They know, and the people generally know, that the arrangements on this coast are wholly inadequate to local needs, and that if the government is to make this branch of its service of general value to the shipping and producing interests of this coast there must be some provision made for equipping a local bureau and a sufficient number of outlying sta-

tions. This has been repeatedly urged upon the attention of Congress by our horticultural societies and mercantile organizations, and has been duly explained by our Representatives at Washington, but no steps have been taken yet. The measures should not be longer delayed. The coast is advancing rapidly in every way, and is continually paying larger contributions to the national treasury. There is every reason why due acknowledgement of these facts should be made by the general government. The subject is fitly set forth by a paragraph in the report just submitted by the Chief Signal Officer in his annual report to the Secretary of War, and which has been transmitted to Congress. He says:

I again call attention to the necessity of a separate office, under the charge of an instructed officer, on the Pacific coast. If a weather service for the country is to be maintained, this important region should not be neglected as it has been. The climatic conditions there differ from those that obtain in the other parts of the country. There are now only 11 stations on the Pacific Coast, and there should be many more, all in charge of an officer with headquarters at San Francisco. In order to carry out its own purposes and the wishes of the people of the coast, the Signal Service must have more officers, more men, and more money than has been given it for the current year.

This is a plain statement of the facts, and it would indeed seem proper that they be no longer disregarded. Not only is this not done, but as funds were short during the past year the Pacific coast was left without any weather service at all during one-sixth of the year. The Signal officer says:

During two months of the year the Pacific coast stations were entirely cut off, for the reduction of \$65,000 in the appropriation for "the observation and report of storms" for the last fiscal year made it necessary to ask the Western Union Telegraph Company to greatly reduce the service which it had contracted to perform, although the terms obtained by this office were based on the agreement that the company should do a certain amount of work. The statute provides that warnings of the approach of storms shall be given by telegraph, and yet the service was left without the means of paying for the necessary telegraphing. The result was not only the reduction in the number of stations to which attention had been already called, but the exclusion of the office from all reports from the Pacific coast for May and June, 1883. This office can do only the work that Congress is willing to pay for. If the necessary data can not be obtained, weather indications will not be so trustworthy as they have been in the past. The number of stations must be increased rather than diminished, if a proper advance is to be made in the art of applying the laws of meteorology for the welfare of commerce and agriculture.

It does indeed seem that this important branch of the government service is being shabbily treated, and it is doubtless true that the people's representatives do not understand the needs of the people in this matter. Probably most of the Congressmen come in no closer contact with storms than can be ward off with a silk umbrella, and they are naturally forgetful of the dangers of the mariners and the losses of the agriculturist, because his products are wholly at the mercy of unheralded storms. Possibly a good storm on the sea or a loss of a crop on land, would give these gentlemen new ideas on this subject.

Notwithstanding the meager and arms-length nature of the service on this coast, it is shown that a creditable amount of good work has been done. The following is the percentage of verifications for the Pacific coast regions for the months given:

DISTRICTS.	1882.					1883.				
	July	August	September	October	November	December	January	February	March	April
North Pacific.	83.3	88.9	94.7	91.7	89.1	85.9	97.0	65.0	93.9	92.7
Middle Pacific.	90.3	98.2	93.8	91.1	85.0	85.7	93.2	92.3	95.6	81.7
South Pacific.	90.3	99.1	98.9	100.0	93.9	96.1	93.2	93.7	94.6	86.5
Total	88.0	95.1	97.4	94.3	86.0	88.2	85.7	89.0	93.8	87.0

The indications for the Pacific coast are for the "weather" only, and for the period the general percentage is 90.5.

We have a host of experienced meteorological observers on this coast who would be pleased to give the results of their experience for the public good. They would constitute a corps of advisers of incalculable value to the Signal Service if their assistance were requested and provided for. The aid of such men, whose observations extend over a period of twenty-five to thirty years, would of course be of greater benefit in making known the meteorology of this new region than similar counselors can be at the East; and yet the Service has such advisory bodies in the older parts of the country. The report to which we have alluded says:

In fifty-four cities meteorological committees have been appointed. These committees confer with the observers of this service and make such suggestions as occur to them for the improvement and development of weather work to the end that it may be of the utmost value to the commerce of the country. These committees are looked upon as important auxiliaries of the weather service, and not only are the observers on stations under orders to confer with them, but it is a standing order that inspecting officers,

on their rounds of duty, also consult them.

Just such provision should be made here. All the wise and experienced observers should be enlisted. The service should be extended. There must be a local office for digesting observations and drawing forecasts. Will Congress provide for this work this winter?

RAIN TABLE FOR SACRAMENTO—PREPARED BY THE LATE DR. T. M. LOGAN AND DR. F. W. HATCH. Arranged according to the seasons, showing the amount in inches of each month, during thirty-four years, and for each rainy season, to Dec. 31, 1883; also the quantity for every month, and the annual amount of rain.

MONTHS.	1840	1850	1860	1870	1880	1881	1882	1883	1884

Total	33.000	0.000	0.000	0.000	0.000	0.000	0.000	0.000	0.000

SPEAKING of the recent "find" in the St. Julien mine, Amador county, which is only three miles from Mokelumne Hill, Calaveras county, the *Calaveras Chronicle* says that several well developed ledges have been discovered and located on the Calaveras side of the Mokelumne river of late, all of which seem to be an extension of the justly celebrated Mammoth mine. San Francisco capital has already taken hold of some of the properties recently discovered.

NOTWITHSTANDING the season, prospectors are working their way into the Cœur d'Alene diggings.

The Nevada Nickel Mines.

As the discovery of nickel on this coast has opened a new field of mining industry, and one which has every indication of becoming equal to the Comstock in richness, the *Record-Union* concluded to gather the facts. In this discovery, as in hundreds of other great finds, these mines have been lying for years within plain sight of the stage road where people constantly travel, without even notice. Samples of the ore have been sent to different assayers for copper, but none ever took the trouble to analyze the rock until it was sent to this city. In 1881 samples of this ore were sent to Charles Bell for copper assay.

Upon examination it was found to contain a large per cent of nickel. More of the ore being secured, it was analyzed, proving the first result. Upon his showing William S. Bell was sent to discover the locations and succeeded in finding the richest and most valuable nickel property ever discovered. The discovery being kept as secret as possible, little was known as to its extent until recently. The property is located in the northern portion of Churchill county, Nevada.

The property has been well prospected and the largest bodies of this mineral exposed that has been known. The nickel ores of Pennsylvania average but two per cent. They are reduced on the ground to fifteen per cent, and sent to Camden, N. J., where they are again reduced and the metal extracted. The nickel found in Oregon has also been opened, but to what extent cannot be ascertained. Thirty tons of the Nevada nickel was sent to London, which graded twenty-nine and one-fourth per cent. These mines are the only ones yet discovered that carry uniformly the three distinct characters, viz: Arsenuret, which is a grayish metallic red; and arseniate, a beautiful apple green; and arsenite, having a dark metallic luster. As developments progress the former characters are merged into the latter, caused by non-oxidation. Several samples showed to reporters have assayed, both by Edwin Booth, of San Francisco, and Charles Bell, of this city, sixty-five and one-half and sixty-six and one-fourth per cent, being the richest ever discovered in the world.

Testing Safety Lamps.

The many accidents which occur in coal mines make the question of relative safety of the various types of lamps one of great interest to miners. A trial of safety lamps and extinguishers at a colliery in Great Britain the other day developed some interesting points. A number of lamps, including the Stephenson, the Davy, Mueseler, Clanny, and the Protector, were examined and found to be in good condition preparatory to undergoing the usual tests in various currents of air. The various lamps were placed in the air-ways, the air passing along at certain velocities, the Davy firing at a comparatively low rate (about 6 ft. per second), proving that it fires at a much less velocity than the other lamps. A Stephenson, in the first instance, stood a velocity of 17 ft. per second before it exploded. This being much higher than the lamp had been known to stand before, it was again tested, and went off at a velocity of 11 ft. per second. What is known as the Smithurst lamp, being a Mueseler with a tin shield, was also tried. The Protector, an adaptation of the Mueseler, stood well for several seconds, then trembled and went out. The experiments, however, were not considered quite satisfactory, and it was agreed that further trials should be postponed until the testing apparatus itself should be proved and made accurate. An adjournment was then made to the surface for the purpose of trying some extinguishers and hose adapted for extinguishing fires in mines. For this purpose three fires were made, so that each apparatus should work independent of the other. Four Dick's extinguishers worked very well, and gave satisfactory results, showing that chemicals can be advantageously used, whilst the apparatus can be taken in any direction and the water thrown where most required. In connection with these extinguishers, it may be said that a number of them can be carried by the men and made to act simultaneously. Foster's chemical engine was set to work and put out the fire. The nozzles of the extinguishers appeared to be only about one-eighth in. in diameter, so that the quantity of fluid poured on the flames was not large. It was very apparent, however, with an ordinary hosepipe with a nozzle 3 in. in diameter, sending a copious supply of water from such an orifice, it extinguished the fire in less time than either of the other two descriptions of machines.

PROGRESS OF ARIZONA.—The *Star's* annual trade review of Arizona shows the population of the Territory to be 85,000, having doubled in three years. The assessed wealth is \$24,200,000 against \$12,000,000 in 1880. The stock increase for the year was 50 per cent. The silver and gold output for the year was \$8,000,000; copper bullion output, 28,000,000 pounds. Peace with the Indians is at last secured, the last of the renegades from Sonora having surrendered to the San Carlos Agency last week. General security is felt, and renewed confidence in Gen. Crook's control of the Indians. There is a general revival of prosperity over the Territory. There are now 98 public schools in the Territory, with a total of 8,500 pupils.

Sudden Outburst of Gas in Mines.

On the occasion of the two most serious explosions in our mines during the present year we are made more familiar with some of the causes which lead to these lamentable catastrophes. Sudden outbursts and blowers, it is said, are the primary causes of most explosions. One of these is believed to have led to the explosion at Moorfield colliery last week, and from the evidence given on Tuesday last at Barnsley with respect to the fatality at the Wharfedale Colliery, it would appear that the gas ignited from a sudden outburst, probably from the roof. At Moorfield a heavy blower was met with in one of the headings, which could not be approached even with the best of safety lamps. The gas came out in large quantities, and it is evident that some of the men who had Davy lamps in endeavoring to escape fired it. This is very easily to be accounted for. In some mines there are large quantities of gas in cavities, and these are at times cut into and the gas escapes as blowers, both from the coal and from the fissures in the strata. It usually escapes in greatest abundance near faults or other irregularities of the beds. It is said that these blowers of gas are never found above the sea level, and when blowers do take place the greatest caution is necessary on the part of the men to ensure their safety. But at the Moorfield colliery some of the men had Davy lamps, and these may have led to the serious loss of life which took place. The Davy lamp usually remains safe unless moved or carried in a current of air; but then when the velocity of the latter is comparatively moderate the flame is liable to pass through the gauze and set fire to the mixture outside of it. It would appear that at Moorfield the Davy lamp was so exposed, at least such is the theory advanced.

At the inquest, which was terminated on Tuesday, at Barnsley, with respect to the seventeen men whose bodies were recovered from the Wharfedale Colliery, the cause was attributed to a sudden outburst of gas, for which the district has been noted. At the Wharfedale Colliery the men were working with "protector" lamps, burning colza-lime; but there was also a Davy lamp in the vicinity of the place where the explosion took place, though it had not been used. Be this as it may, there was a vast accumulation of gas—an extensive outburst, in all probability, from a crosscut on the main air-way course; but whence it came there was no evidence to show, the probability being that gas was liberated in large quantity, and that the outburst affected the velocity of the air, thus bringing out the flame of a lamp to the explosive mixture. The result of the evidence given was certainly by no means satisfactory, even to the jury, who returned a verdict that the seventeen persons brought out of the colliery after the occurrence were killed by an explosion of gas, but how it was caused there was not sufficient evidence to show. In conclusion, it may be said that, as blowers and outbursts take place suddenly, and from places least expected, it is impossible at all times to guard against them. All that can be done is to work fiery mines with lamps that will be self-extinguishing in an explosive atmosphere.—*London Mining Journal*.

Very Young Quartz.

It is a generally accepted theory that quartz, sandstone, slate, etc., are geological formations which require thousands of years to form. A few days ago, in Virginia City, Conductor Havenor showed the editor of the *Appeal* a specimen of quartz which never could have existed over fifteen years ago. The quartz in question was taken out of the Yellow Jacket mine from between the timbers. The timbers were put in fifteen years ago, and the material forming the quartz had apparently oozed through a crack and adhered to the timber. It was about the size and had the appearance of a cauliflower. There was a mass rather soft and crumbling to the touch, and in places woven together like threads, and in this mass, and a part of it, were three distinct and perfectly formed quartz crystals. The mass had been pushed through the crack while in a plastic state, and then formed in the bunch described. The specimen in the possession of Mr. Havenor shows where it adhered to the timber.

He also has a piece of sandstone taken from the creek at Stevens' mill, near Dayton. The mill was built twelve years ago, and a portion of a wooden stake driven into the ground at the time is solidly imbedded in the sandstone, which is as firm and hard as any sandstone of the old sandstone period. There is a rusty nail in the wedge.

About twenty years ago a spring was dug on American Flat. Week before last it was found that a hard stratification of slate had formed on the bottom. It was broken up with an axe, and Mr. Havenor secured some good specimens. The slate was half an inch thick, perfectly hard and brittle, and had adapted itself to the conformation of the spring, where it had formed like scales on a teakettle.

Will some geologist explain how the theory will hold water that all these classes of rock are the result of thousands of years of chemical action.—*Carson Appeal*.

The Plymouth Consolidated Company, of Amador county, has 100 stamps in operation, and is paying its monthly dividend regularly.

USEFUL INFORMATION.

Photographing on Linen and Silk.

A Detroit photographer says: "There is this feature about photographing on linen: You can wash and boil the work and it won't come out. There is some special interest shown among society people just now on this subject, because of some napkins used at the banquet given to Henry Irving, the actor, before he left London. His photograph was on each one, and, of course, it was intended as a souvenir for the guest to take away with him. The silk or cambric is printed from the negative. There will be a rage for it if it once gets started, and people will have photographs printed on their curtains, and tidies, and in handkerchief corners. The face of a beautiful young lady on the corner of a gentleman's handkerchief, would be much more attractive than a monogram or initial letter. It would be just the thing for hat linings and bands." The *Detroit Free Press* suggests that not the least of the advantages of such photographing would be that the wash would be promptly returned if the missing pieces were to haunt the wretched landress with a vision of her customers.

TO KEEP GILT GOODS BRIGHT.—Stationers always have more or less loss in gilt goods and it is no easy matter to keep these gilt goods bright and clean. The following is a good recipe: Gilt articles, if of metal, may be cleansed by rubbing them gently with a sponge or soft brush moistened with a solution of half an ounce of potash, or an ounce of soda, or perhaps best, an ounce of borax, in a pint of water; then rinsing them in clear water and drying with a soft linen rag. Then luster may be improved in certain cases by gently heating them, and then applying gentle friction with a soft rag. A very diluted solution of cyanide of potassium will answer the same purpose by applying in the same manner as above, washing in water and finally drying by gentle friction with a linen rag; but as this substance is very poisonous, it is not to be recommended for household uses. Gilt frames of mirrors, pictures, etc., should never be touched with anything but clean water, gently applied with a soft sponge or brush.

CHANGING THE TRACK OF TORNADES.—A correspondent of the *Scientific American* proposes the following method for changing the track of tornadoes: Take one keg or barrel of common rifle or cannon powder to the limit of your city or town where it is approached by a tornado. Fix it to an artillery priming tube, having a string to it about 100 yards long. Take your position at the end of the string, holding it taut. Wait till the tornado seems to be precisely over the powder, then fire the powder by pulling the string, and if the charge is large enough, that gyrating, whirling tornado will be effectually blasted out of existence; at least, made harmless till blown beyond your town, where, perhaps, it will reform itself. If the tornado could be advertised a few hours before its appearance, giving time for preparation, the suggestion might possibly be valuable.

NEW USE FOR ASBESTOS.—Powdered asbestos is made by M. Erichsen, of Copenhagen, for making a special enamel or coating. It is mixed with soluble salts, such as silicate of potash and mineral or other colors, which combine with the silicic acid so as to form a product which withstands the action of oxygen, heat and atmospheric changes. This substance furnishes a refractory glazing, which protects porous materials, and which can be applied to wood, to gas or water pipes, to brick walls and to constructions of stone or cement. When it is employed on masonry or on wooden articles, the surface is first washed with soap and water. In the manufacture of this enamel or paint, it is only the refuse of the asbestos which is employed, and this refuse, it is said, would be worthless for any other purpose.

HOW FIRE MAY BE CARRIED IN COTTON.—Edward Atkinson, of Boston, says: "Fire lurks in a cotton bale for weeks. The cotton which was injured somewhat over a year ago in Biddeford, Me., was moved to South Boston for sale. The fire broke out again more than once while it was at South Boston being made ready for sale. It was then sold at auction. The fire broke out again in one parcel while it was on the cars being carried away, and in another parcel after it had been received at a factory where it was to be used. The latest outbreak was, I think, thirty days after the original fire."

ABOUT WAGON WHEELS.—The *Farmer's Review* says: I have a wagon on which, six years ago, the felloes shrunk so that the tires became loose. I gave it a good coat of hot oil, and every year since it has had a coat of oil or paint, sometimes both. The tires are tight yet, and they have not been set for eight or nine years. Many farmers think that as soon as wagon felloes begin to shrink they must go at once to a blacksmith shop and get the tire set. Instead of doing that, which is often a damage to the wheels, causing them to dish, if they will get some linseed oil and heat it boiling hot and give the felloes all the oil they can take, it will fill them up to their usual size and tight-

ness, keep them from shrinking, and also keep out the water. If you do not wish to go to the trouble of mixing paint you can heat the oil and tie a rag to the stick and swab them over as long as they will take oil. A brush is more convenient to use, but a swab will answer if you do not wish to buy a brush. It is quite a saving of time and money to look after the wood work of farm machinery. Alternate wetting and drying injures and causes the best wood soon to decay and lose its strength unless kept well painted. It pays to keep a little oil on hand to oil fork handles, rakes, neck-yokes, wheel-trees, and any of the small tools on the farm that are more or less exposed.

A FIRST CLASS violin has seventy separate parts. Two form the back, two the belly, six the blocks, six the sides, twelve the lining, twenty-four the purfling, and there is the tail-pin, its pegs and fastening, the tail-piece, the bass-bar and sound-post, the bridge, nut, head and scroll, the finger-board, and the four pegs and four strings. The body weighs about half a pound, with the neck and scroll about twenty ounces, and when tuned to pitch the pressure on the bridge is over ninety pounds.

THE NEW HOOP MACHINE.—It is claimed that the newly invented Boston hoop machine will make from 20,000 to 30,000 half round hoops a day, cutting two, three or four from a pole, as occasion requires. One of the results of the introduction of this new machine will be the utilization of ironwood saplings for hoops. This tough and almost indestructible wood, which resists the tools of the cooper, is said to be handled without difficulty by the Boston hoop-making machine.

SINCE the adoption of standard time about 400 applications for patents have been filed for clock dials and other devices intended to present the twenty-four hours in a convenient manner and without unduly crowding the figures. A large number of these applications have been rejected by the Patent Office upon evidence found in an old volume that Prince Soltykoff once possessed a watch, made in 1547, on the dial of which the hours from 1 to 24 are arranged in two concentric circles.

A CAMEL has a foot furnished with a pad, which resists the burning sand of the desert for years, which would wear out a horse's hoofs in a few weeks.

A SINGLE leather belt, one inch wide, traveling 800 feet per minute, will transmit one horse-power, provided the pulleys are both the same.

GOOD HEALTH.

Philosophy of Eating.

Were men to exercise the same judgment in regard to their own food that they do in feeding domestic animals, there would be less illness on account of errors of diet. For a matter of such universal importance it has been the subject of many absurd theories.

The world seems to be divided between those who "eat to live" and those who "live to eat." The proper line may be drawn somewhere between these extremes. There is little to choose between a glutton and one who eats too little from a sentimental notion that it is vulgar to eat; and that the less one can eat, and still manage to live, the more refined and spiritual one becomes. If a man has no control over his appetite, and no judgment as to the quantity of food he requires, it would have been better had he belonged to a lower order of animals, subject to the control of a higher intelligence. Neglect or refusal to partake of sufficient food to sustain the body in its full vigor should be regarded as evidence of disease, requiring the attention of a competent physician. Nature will not patiently submit to be abused or cheated.

The quantity and quality of food required in each individual case depends on the size and health of the person, and on his occupation. A person of sedentary habits should regulate the diet to the requirements of the system, remembering that it is safer to err on the side of eating hardly enough than too much. Over-eating produces accumulation of fat, which is a disease of itself, and increases the quantity of blood, rendering one liable to heart disease and apoplexy; and paradoxical as it may seem, insufficient food tends to produce the same diseases. Either condition causes derangements in the circulation that may induce some troubles.

If we follow the indications of nature we are safe as to foods. What the appetite craves is usually best for us; the stomach notifies us when we require food, and when we have eaten enough. It is often the last mouthful that invites an attack of dyspepsia.

"Variety is the spice of life." In nothing is this more applicable than as to foods. Select a list of foods that experience has taught us are most acceptable, and then from the list get a variety for each day of the week. Salt meats should be used sparingly, because they are more indigestible than fresh. Pies and rice puddings try the digestive organs severely, and cannot be safely indulged in by adults, except they have vigorous out door exercise. The quantity and quality of food should depend upon what is required of the individual; just as the amount of

fuel requisite depends on the work a steam engine has to perform.

A wise regulation of the food supply can be made to supersede the use of medicines to a very great extent.—*Journal of Health*.

INTERIOR PROPERTIES OF VANILLA BEANS.—A distinguished Professor of the Faculty of Medicine of Bordeaux, Dr. Layet, has, says the *Lancet*, just read an interesting communication on certain injurious properties of vanilla, of which a satisfactory explanation has up to the present been wanting. The affections have been studied at a warehouse in Bordeaux, where on an average 25,000 to 30,000 kilograms of vanilla arrive every year. In these storerooms the pods are cleaned, sorted, and classed according to their quality. These manipulations seem to cause certain symptoms among the workmen and women. At first an itching of the face and hands associated with a powerful smarting sensation is experienced, and the skin becomes covered by a pruriginous eruption, swells, reddens, and desquamates at the end of some days. At other times there is a feeling of malaise with dullness, stiffness, and muscular pains, which oblige the worker to give up this kind of labor. The cutaneous malady seems to be due to an acarus which appears as a small, white, rounded body occupying generally the ends of the pod. This insect does not penetrate the skin like the *Acarus scabiei*, but determines the affection by its mere contact. Probably the parasite is aided in its irritant effects by the presence of "givre" in the form of pale acicular crystals. The nervous symptoms M. Layet is inclined to put down to the manipulation of inferior pods of vanilla containing much oily juice enveloping the seeds in the interior of the silique.

WHEN TO TAKE MEDICINE.—The chief causes of disease are errors in diet, errors in dress, intemperance, impure water, unwholesome food, defective teeth, and blood poisoning from inhalation of impure air and noxious gases. Disease induced by any one of these causes, almost invariably manifests itself by disorder in the functions of the liver; there the alarm is sounded first, and if not attended to promptly the trouble is liable to extend to other vital organs. Dyspepsia, constipation, chronic diarrhoea, disease of the kidneys, dropsy, rheumatism, catarrh, consumption and various forms of skin diseases often proceed directly from derangement of the liver. Attention to the liver forestalls other diseases. The remote cause of a majority of our ordinary ailments, is taking cold; the natural functions of the body are retarded, and waste material is retained in the system long enough to do mischief. The usual remedy is to take a cathartic or a laxative in order to remove it. But a more convenient and a more natural plan, in ordinary cases, is to cut off the food supply for twenty-four hours, and trust to nature to do the rest. Instead of food, a few teaspoonful of hot water drunk during the day will hasten the desired result. Whenever the bowels become constipated there is an uncomfortable feeling in the system, often accompanied by restlessness and anxiety of mind. The above suggestions, if followed strictly, will bring relief more promptly than medicine and without its inconveniences.

THE INCREASE OF INSANITY.—The increase of insanity is not confined to this country. In 1868 the number of lunatics reported in France was 34,000; to-day it is nearly 60,000. It should be remembered, however, that such statistics presumably become more accurate and complete every year, and moreover, that many a person is now pronounced insane who would have been considered merely eccentric fifteen years ago. There are 103 lunatic asylums in France, of which 61 are public and 42 private.

TO TEST THE PURITY OF WATER.—If you think the water you use regularly for drinking is impure, try the following test: put one and a half pints of water into a clean glass bottle; add to it a teaspoonful of pure white sugar, cork it and shake until the sugar is well dissolved and then set in a warm place for 48 hours. If it is unfit for drinking it will be turbid and milky at that time.

WE BEAT THE WORLD ON DOCTORS.—The proportion of doctors to the population in different countries is given as follows by the *Siglo Medico*: France, 2.91 per 10,000; Germany, 3.21 per 10,000; Austria, 3.41 per 10,000; England, 6 per 10,000; Hungary, 6.10 per 10,000; Italy, 6.10 per 10,000; Switzerland, 7.06 per 10,000; United States, 16.24 per 10,000.

A LINIMENT FOR RHEUMATISM.—The *Therapeutic Review* says: Methyl salicylate (oil of wintergreen) mixed with an equal quantity of olive oil or linimentum saponis, applied externally to inflamed joints affected by acute rheumatism, affords instant relief, and, having a pleasant odor, its use is very agreeable.

LUPINOSIS.—C. Arnold has extracted from lupus a shining brown solid matter of pleasant aromatic odor and taste. In water it dissolves slowly, forming a turbid solution. In doses of ten grammes it produces the usual symptoms of lupinosis, especially acute jaundice.

BRAIN WEIGHT.—The average weight of the brain of a man is three and one-half pounds; of a woman, two pounds and eleven ounces. The brain of a man exceeds twice that of any other animal.

SAN FRANCISCO:

Saturday Morning, Jan. 12, 1884.

TABLE OF CONTENTS.

EDITORIALS.—Chisholm's Improved Sawmills; Mining not Stopped, 17. Passing Events; The Debris Decision; Carbonate and Oxide Copper Ores; Condensing Fumes from Furnaces; Mining Improvements, 24. Yankee Fork and Bay Horse Districts, Idaho; Lane Lectures; Mining Debris, 25. The Bullion Product, 29.

ILLUSTRATIONS.—Chisholm's Improved Patent Lever-Saw Circular Sawmill, 17. Yankee Fork and Bay Horse Mining Districts, Idaho, 25.

CORRESPONDENCE.—San Francisco and Pine Grove Mining District; Affairs in Mexico, 18.

MECHANICAL PROGRESS.—The Cinder of Wrought Iron; Some Curiosities of Steel; A New Welding of Flux; Hardening Steel; Polish and Case Hardening; A New Project for Chilling Iron, 19.

SCIENTIFIC PROGRESS.—Vegetable Evaporation—Improvement of Land; Temperature of the Sun; The Sunset Colors; Photographic Progress; Compensative Heat Employed by Different Lights; National Museum of Entomology; Agricultural Value of Entomology; Sand and Water, 19.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 20-21.

USEFUL INFORMATION.—Photographing on Linen and Silk; To Keep Gift Goods Bright; Changing the Track of Tornados; New Use for Asbestos; How Fire may be Carried in Cotton; About Wagon Wheels; The New Hoop Machine, 23.

GOOD HEALTH.—Philosophy of Eating; Injurious Properties of Vanilla Beans; When to Take Medicine; The Increase of Inequality; To Test the Purity of Water; We But the World on Doctors; A Liniment for Rheumatism; Lymphitis; Brain Weight, 23.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Meetings, Assessments, Dividends and Bullion Shipments, 29.

NEWS IN BRIEF.—On page 29 and other pages.

MISCELLANEOUS.—Systems of the Crucible Assay; To Cheapen Mining Patents; The Cour d'Alene Placers, 18. Platinium; The Signal Service; The Nevada Nickel Mines; Testing Safety Lamps, 22. Suden Outburst of Gas in Mines; Very Young Quartz, 23.

Passing Events.

The decision in the famous debris suit, which was rendered this week, is the most important thing to the miners of the State of California which has occurred for a long time. We give a full abstract of the decision, and speak of the subject in another column.

The tables of bullion product printed elsewhere show a yield of over ninety millions of dollars from the mines last year. There is not much change in California figures, though what there is notes a falling off. The mines in San Bernardino county and that region will help out the year, though the cessation of hydraulic mining consequent on the injunction will greatly decrease our bullion product.

We intend next week publishing a double edition of the PRESS, the space in which will be mainly devoted to a review of last year's mining work.

In the Tabernacle at Salt Lake, Apostles Cannon and Woodruff both declared that Mormonism, in all its features and doctrines, would be continued, whatever Congress or the country might threaten, and that the progress of the church could only be stayed by killing all the saints.

THE Queen contemplates shutting up Buckingham Palace still further. It is now used as an occasional town house by several of her children, and this she finds expensive.

The Debris Decision.

It seems strange that in California, known to the world's end as the "Land of Gold," any branch of mining should be declared a public nuisance. Yet this is in effect what has been judicially pronounced, by the decision just rendered, and an abstract of which is published in this number of the PRESS.

When, in 1849, the fabulously rich placers of the State of California astonished the world by their productiveness, a new and progressing industry was born to these United States. The first steps were then taken towards establishing mining on the basis on which it has since stood. The influence of those few yellow grains found in the tail race of Sutter's mill was far-reaching. From that little rill grew a broad and golden stream which spread in all directions to the very end of the earth, and which, while it carried prosperity and wealth to those beyond our borders, enriched as well the dwellers at the source. When the news of the discovery of gold in California flashed like wildfire through the settled and steady-growing regions on the Atlantic side of the continent, the electric spark kindled into life and being the spirit of adventure and change only among the bravest, most hardy, and enterprising of the land. These, a chosen band, selected by the Spirit of Progress to found a new empire by the Western sea, threw aside all habits, customs and traditions to build new homes and found new communities in a land before tramped only by the cloven hoofs of cattle or the moccasins of the aborigine. With toil and labor, through difficulties and danger by sea and land, they came the thousands of miles stretching between them and the Land of Promise. The weaker dropped by the way—the fevers of the isthmus, the Indians of the plains and the stormy terrors of Cape Horn claiming victims from every band. These men came for gold. They came too, with the purpose of taking up those occupations which cluster about a mining community. But mining was the paramount interest, and was the foundation on which this great State was built. The golden millions poured in steady and branching streams over the summits of the mountains and back to the homes in every nook and cranny of the nation. Men saw such opportunities for enrichment as they had never before dreamed. The influence of the golden grains gathered from the sand, gravel and earth of California's surface was magical. They brought thousands and thousands of men, women and children to these shores to stay; to build up villages, towns and cities; to establish a great commercial center, and make a country world-renowned for its productiveness and resources. From here they spread along the ocean and back from it, until other States and Territories were organized and formed. Nevada, Idaho, Montana, Utah, Oregon, Washington, Arizona and New Mexico might still have been in their original wilderness but for California gold. The settlement of the most progressive and prosperous section of the United States is the direct result of the mining industry. Mining has led; Agriculture has followed; and in some cases the latter has grown to overshadow the other. California was the pioneer in the great mining industry of the nation, as her people were the pioneers of the Pacific coast. For all these years the mines of this State have been steadily worked, and from the experience gained have grown new systems, new machines and new plans for adding to the world's wealth, which have been copied and followed wherever mining is pursued.

And now comes a Judge who says, in effect, that hydraulic mining, from which has come the bulk of California's gold for many years back, is a public nuisance. The older Californians who have grown up with the State will hardly believe that such a thing could come to pass. It is not worth while now to review the causes which have led to this decision. Every argument for and against hydraulic mining has been advanced; eminent lawyers have been employed; hundreds of witnesses have been examined; experts have given their testimony; interested parties have expressed their opinions; associations have done their work; the case has been tried; the decision rendered; and it is that hydraulic mining must stop.

But it will be proper to briefly consider what will be the effect of the decision upon the miners. They are law-abiding people, and what-

ever hardships they may consider they have undergone, they will submit to the dictates of the law and stop their work. Their mines will be closed down; their tools put away; their dams left open; and, in many places, their homes abandoned. In a great battle they have been defeated.

One gleam of light remains for them. The Judge declares that if it can be shown that the debris can be properly controlled and impounded, opportunity will be given to have the injunction dissolved. Moreover, there is this: Judge Temple decided that debris dams being built, and the heavier sediment caught, hydraulic mining could go on. Judge Sawyer decides hydraulic mining a nuisance. The case has been appealed and the Supreme Court of the United States will yet finally decide which of these two decisions is right.

But this may take years. The Supreme Court is, unfortunately, notoriously slow. The hydraulic miners in the section affected must now obey the injunction of the court and stop their work. Thousands of men will be thrown out of employment; and equally serious is the fact that many communities which have depended on this industry will be broken up. Of course the gold product of the State of California in 1884 will be greatly reduced by the stoppage of these mines. Some of them will be worked by the drifting process, in all probability, but the great majority of them cannot be so worked profitably.

The misfortune falls on a community generally remarkable for their intelligent, noble and generous disposition, and even among their bitterest enemies sympathy is felt for their condition. Years ago not the most far-seeing man could have foretold such a result as this, as no parallel case has occurred in the world's history.

Carbonate and Oxide Copper Ores.

About two-thirds of our copper comes from the Lake Superior region of the United States, and about one-half of the remaining 30,000,000 pounds comes from the carbonate and oxide ores of Arizona, New Mexico and California. More skill is required, of course, in getting a yield out of the sulphureted ore than in the simple melting and refining, which is all that is demanded in the production of copper from its metallic or oxidized condition.

The ordinary American practice in the treatment of carbonate and oxide ores has been almost entirely built up within the past ten years, and, owing largely to the perfection of the water-jacket furnace and the use of simple fan blowers, it is economical and satisfactory. The ore is so sorted at the mine—where necessary—as to yield at least ten per cent copper; and after having been worked to egg size by a jaw-crusher, is fused in the water jacket furnace with coke as fuel, with the addition of the necessary fluxes, limestone, iron ore or quartz.

Many of the deposits occur in a limestone country, and contain more or less oxide of iron, so their reduction is simple. Some of the deposits, however, which carried their entire copper contents in an oxidized condition, are now showing a considerable proportion of copper glance and other sulphur compounds; and the unwelcome sight of an increasing quantity of matte is beginning to complicate the hitherto almost unparalleled simplicity of the process. At some works it has been the habit to recharge this into the furnace, a highly unscientific and expensive practice, as it merely adds to the fuel used, and in nowise increases the metallic copper production, except in so far as it may become slightly oxidized, and a small part of its sulphur volatilized in its passage through the furnace. At other works it is sacked and shipped East, but this is expensive. The metallic product of these furnaces is shipped East to the refining works, in the shape of black copper, assaying usually from 94 to 98 per cent; and the competition for this class of material, and the favorable rates for pig copper as compared with ingot, bears little inducement for the establishment of refining works in the neighborhood of the mines.

The Four Hills mine, in Plumas county, which in a month or two yielded more than \$100,000, was crossed by a trail which has been traveled every summer since that county was inhabited by the white man, and at one time a shaft was sunk within a few inches of the rich deposit.

Condensing Fumes from Furnaces.

Mr. E. M. Alderman, of Tucson, Arizona, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a fume-condensing attachment for ore furnaces and smelters, a description of which will be of interest to furnace men. The invention consists in a novel means for introducing a fine spray of water among the vapors and fumes as they pass along to the exit. The fumes are allowed to pass from the stack of the furnace into a pipe suitably supported, and inclined slightly below the horizontal. At one end it has a discharge, and a continuation vertically, to serve as the exit for the smoke. Supported above this pipe is a water-distributing pipe, supplied with water under pressure. Let into the condensing pipe at suitable intervals are small pipes having an elbow shape, their horizontal arms, which occupy a position about the center of the circumference of the condensing pipe, being finely perforated. These pipes are connected by hose and coupling with the water pipe so as to be removed readily when repairing or cleaning may be necessary.

The water under pressure is forced out through the finely perforated pipes in minute streams, almost spray of themselves, and, coming in contact with much force with the sides of the condensing pipe, the water breaks into spray. Through the spray the fumes and vapor from the furnace have to pass. None can get by without becoming thoroughly saturated with moisture and condensed. The spray being applied only at intervals, clear space is left between each spray pipe, and the spray, which is carried forward by the current, has time to be thoroughly absorbed by the fumes before they pass through the next spray.

The condensing pipe being practically horizontal, there is no necessity for various retarding and obstructing devices as are used in certain kinds of smoke condensers, where the condenser is vertical and showers of water fall thereon. The condensing pipe in this is free for the draft to advance the fumes from one spray cloud to another, having clear space and time to effect complete absorption and condensation. The slight incline of the pipe carries off the condensations. It is the arrangement of the system of spraying that the patent covers. The use of water for condensing is not new, of course, but this precise plan of using it is covered.

Mining Improvements.

Mining has been placed on such a basis that anything that tends directly or indirectly to lessen cost of production is eagerly adopted, not as a passing fashion, but with the earnest purpose of keeping abreast of the times. In this country we are constantly at work devising means for improving the mechanical appliances of mining. Hoisting and pumping machinery, cages, cars, pans, mills and all such things are being continually simplified and improved.

In Europe the same tendency is apparent. Here the improvements are not only in the general design of machinery, but in its details or construction and erection. A noticeable feature in Belgium, for instance, is in the reduction of the dead weight in coal tubs and cages. This is everywhere being effected with all the speed that the capital at disposal admits of. The means by which the reduction is being brought about are, first, the improvement of the general design, and the details of the construction of these portions of a colliery plant; and second, the substitution of steel for iron. By the use of steel plates for coal tubs, remarkably light vehicles are produced. In one colliery where this change has been carried out by the gradual substitution of steel tubs for the old wooden ones, the ratio of the dead to the total weight has been reduced from 69 to 40 per cent. The old iron drawing cages are being rapidly replaced by improved steel constructions. These differ somewhat from existing types, and they certainly combine the maximum of strength and rigidity with the minimum of weight. Some recent accidents have again raised attention to the question of safety catches on cages. Much ingenuity has been fruitlessly expended upon these mechanical devices for preventing the fatal consequences of a broken rope, if we are to judge from the great number of contrivances proposed, and the fact that none have been commonly adopted.

NEEDLES has organized a "101" Committee of Safety, and the citizens mean business.

Yankee Fork and Bay Horse Districts, Idaho.

The map on this page shows an outline of both Yankee Fork and Bay Horse districts, in Custer Co., Idaho. In this county the chief mining districts are found on the Salmon river and its tributaries. Bay Horse district, in the eastern part of the county, contains some very important mines, the best developed of which is the Ramshorn. This is an immense ledge, on which are a number of producing mines, such as the Utah Boy, Post Boy, Mono, Juliet, Vermont, Broadway, Redemption, Silver Bell and Quincy. The Ramshorn was the first location. The vein is from two to six feet wide, in slate formation, and the ore contains chloride, gray copper and lead. The mine is worked below 800 feet in depth by means of tunnels. In the last report of the Director of the Mint is an account of the mines of the district, from which we make the following extracts:

Bay Horse District.

The Utah Boy is the first extension south of the Ramshorn, and is owned by the same company. The Post Boy is next to the Utah Boy, and is opened by tunnel. On the Juliet mine a tunnel has been driven 990 feet, and a shaft sunk 135 feet. The ores are quite similar to those found in the Ramshorn. The Broadway mine is located on Poverty Flat mountain;

smelters in operation, or ready for work in this district. The Bay Horse Mining and Smelting Co. have a 20-ton smelter on Bay Horse creek, under the management of Mr. A. J. Crook.

The Salmon River Mining and Smelting Company's smelter, situated on the banks of the Salmon river, at Clayton, has a capacity of about thirty tons. The mines of this section, taken as a whole, are of a promising character, and will doubtless make large out turns of bullion; but few sales of mining property have been made, and but little outside capital has been employed in their development, and yet they have been steadily opened and have made fair returns for the time and labor expended.

Yankee Fork District

Includes the mines located upon the Yankee Fork, Jordan creek, and the adjacent mountains, Estes Peak, Norton Hill and Custer Hill. The principal mining camps are Custer and Bonanza City; the first situated near the junction of Jordan creek and Yankee Fork, and the latter some six miles down the Yankee Fork, near its confluence with West Fork. The Custer mine is located about half a mile from Custer City, at an altitude of 8,200 feet above sea level. Here, by an inexplicable freak of nature, seldom witnessed, from that portion of the ledge heretofore worked, by erosion or other causes, the hanging wall has disappeared, leaving the ledge smooth and unbroken, and having the

wagon road. This mine was discovered as early as 1876, by W. A. Norton, who commenced work in a small and rude way. With two assistants he made an open cut, and the ore taken from it was crushed in hand mortars and yielded a very large sum. The upper tunnel was started in 1877, and the ore extracted was shipped to Salt Lake City. An adit was built in 1878, since which time, except a portion of 1881, it has been continuously run. The yield during 1882 was reported as having been \$80,000.

The Pilot group of mines adjoins the Dickens on the west, and are the property of an Eastern company. Estes mountain is about six miles from Bonanza City, near the source of Jordan creek. The principal mine is the Montann. The character of the ore is a sulphuret and chloride of silver and gold, about two-thirds of its value being gold. Since its discovery the mine has shipped to Omaha, Salt Lake, the Bay Horse smelter, and other markets, high grade ore to the value of a quarter million of dollars. The value of the ore shipped ranged from \$500 to \$1,200 per ton, during 1882.

The Snowbird, Pioneer, Charles Wain and Cynosure mines lie parallel with the Montana, and about 600 feet distant. These veins are bold and prominent and can readily be traced over the apex of the mountain for about 500 feet. This section requires more milling and

Mining Debris.

A Decision in the North Bloomfield Case.

Judge Sawyer this week rendered the long expected decision in the case of Woodruff vs. the North Bloomfield Gravel Mining Company. It makes the injunction perpetual, virtually prohibiting hydraulic mining. The decision is very voluminous, but we give a full abstract as follows:

This is a bill in equity to restrain several mining companies on the western slope of the Sierra Nevada mountains from discharging their debris into the Yuba river and its alluvials, by which it is carried into the Sacramento and Feather rivers, filling them up and injuring their navigation, and sometimes injuring neighboring lands by overflowing and covering them with debris.

Lieutenant Colonel Mendell's report to Congress in January, 1882, on the injurious results of hydraulic and other mining, will furnish many of the facts relied on, since it has been recognized by both sides, and the remedies it suggests being confirmed by other evidence. In 1855 the water which carries away the earth and debris of a gold-bearing bank was discharged through a rubber hose, with nozzles of not more than an inch in diameter; by later machines the nozzles' size and pressure were largely increased. Now, for instance, an eight-inch nozzle at the North Bloomfield mine discharges 185,000 cubic feet of water in an hour, with a velocity of 150 feet per second. At some of the hydraulic mines the "Monitor" machines are worked night and day.

The Yuba River Drains

About 1,330 square miles of Sierra, Nevada and Yuba counties. Its basin's highest elevation above tide water is 8,000 feet; its lowest, 200 feet. The debris complained of is mostly discharged into its tributaries. Colonel Mendell says that 700,000,000 cubic yards may be assumed to represent the amount of gravel remaining to be worked by hydraulic process tributary to the Yuba. The beds of all the streams mentioned, from the very dumps of the higher mines to the junction of the main Yuba with Feather river, have been filled up at some places to a depth of 150 feet, and all have regularly graded themselves, so that a railroad track might be laid upon their beds for the whole distance. Their channels are choked and clogged with debris. Most of it will from year to year be carried further down, and ultimately to the valley. The ordinary annual floods are unable to carry all of it off, and it accumulates in vast amounts. Any extraordinary flood that may occur will sweep it into the valleys. The Yuba's load of sand and gravel has risen until it now stands above the level of the adjoining country on either side. This eruption from the mountains has destroyed over 15,000 acres of alluvial land. Before hydraulic operations commenced, rich, black bottom lands extended on each side of the Yuba, and on them were some of the finest farms, orchards and vineyards in the State. These have been ruined by debris and abandoned. Levees were built along the ridge on either side of the Feather river, but they broke and Yuba county was flooded. The filling of debris between the levees is several feet above the level of the surrounding country on the outside. The filling gradually rises as the river is ascended till, at Squaw Flat, by the entrance of the foothills, it is 150 feet deep. This change in the depth of the water has impaired the practicality of navigation. Greater exposure to overflow now exists for all riparian lands on both these rivers. For years the comparatively deep draft steamers, Senator and New World, ran regularly through Steamboat slough. It is not navigable now for light draft river boats of to day, and its navigation has been abandoned.

The River Channels

Have been largely contracted in width. The filling up of the present navigable rivers is threatened. The Yuba waters are so charged with debris that they are wholly unfit for watering cattle, domestic or other uses, unless first taken up and allowed to stand and settle. As it comes down to Marysville it is so charged with sand as to be unfit even for surface irrigation. Two dams for unbounding debris were constructed by the State, under the Drainage Act of 1880, at a cost of \$500,000. Both were destroyed. A dam made by the North Bloomfield Mining Company at Humboldt canyon is full, and the debris has passed over and filled the canyon and South Yuba to a level with the debris above, as if no dam existed. A dam across Sucker Flat ravine is in a similar condition. The plaintiff owns property in Marysville and two farming tracts on the Feather river. The latter have become useless through being buried by debris, and by an overflow, caused by debris, his Marysville property was injured in 1875. The level of the bed of the Yuba was elevated by these deposits above that of the basements of Marysville buildings, and as the water in them rises and falls with that of the river, they were rendered unfit for use and abandoned. The sewage was greatly obstructed by the same means.

The Filling Up by Debris

Caused a greater flood, with a smaller amount of water in 1875 than in 1881. In 1881 the inhabitants of Marysville were called out in the

(CONTINUED ON PAGE 28.)

YANKEE FORK AND BAY HORSE MINING DISTRICTS, IDAHO.

about fifteen tons taken from a forty-foot incline averaged, by smelting, \$260 per ton. The other mines on this lode are all similar, the ores being the same in general character and value. On Ramshorn mountain, and west of the Ramshorn mine, are located the Excelsior, Beardsley, Hood, Keno, Goodenough, River-view and Eagle Rock on Bay Horse creek; and Colorado Kid, Uncle Ben, Melrose and Head Light on Garden creek. The Excelsior is opened by two tunnels of 85 and 125 feet respectively. From the second or main working tunnel a crosscut 40 feet in length taps the whole length of the ore body, which is a high-grade carbonate; average assay of 90 ounces per ton. The other mines of this group on Bay Horse creek contain the same character of ore, but not of quite so high a grade.

The group on Garden creek, about 6 miles west of the town of Challis, are similar to the first named group. The formation here is lime. The Kinnikinick mines are represented by the Monitor, owned by Capt. C. B. Rustin; the Overland, owned by J. D. Wood & Co.; the Silver Moon, Lone Star, Ella and War Eagle, owned by different parties. The Squaw creek mines are principally owned by J. D. Murphy & Co., a New York City firm, Capt. C. B. Rustin and Messrs. Conover & Gantt. But little has been done the past season on any of the locations, but what has been done places them on a par with the best in this district. These mines, as also those on Kinnikinick creek, lie in limestone, the same belt as the Bay Horse and Garden creek properties. There are two

appearance of a vast quarry of quartz on the mountain side. A tunnel has recently been started to tap this immense ore clute at a depth of 250 feet below the surface.

The mine is connected with the mill by a Hallidie wire tramway. The mill contains thirty stamps. This mill ranks as the best and most convenient silver mill in the territory. The mine and mill are the property of Messrs. Haggin & Grayson, of San Francisco.

The General Custer ores, like most others in the district, are sulphurets of silver, carrying from 10 to 20 per cent. of their value in gold, and are treated by first chloridizing and then amalgamating in the ordinary way.

The Custer mine has produced about \$2,000,000 worth of bullion; the last year's production is reported to have been \$850,000. The ore producing this amount has been taken from open cuts.

The Unknown mine adjoins the Custer on the east, and is a continuation of the same ledge. The Bureka, Continental, and Badger lie eastward from the Unknown. The Badger is opened by about 1,800 feet of shafts, etc., and has yielded a large amount of high-grade ore; the production during 1882 was about \$30,000.

The Little Giant, Black Crystal, Three-timeloser, and Bluewing extend south from the Badger and are promising ledges. The Lucky Boy and Anna adjoin the Badger on the west.

On the opposite side of the Yankee Fork from the Custer mine, and about a mile distant, is the Charles Dickens mine, situated at an altitude of 7,300 feet, but accessible by a good

reduction facilities, which, when supplied, can not fail to attract attention to the district for its large production of bullion.

All the mining camps of Custer county, situated north of the Salmon river, procure their supplies from the town of Challis, which, from its location, is destined to be one of the leading towns of Idaho. It is situated in Round valley, which has a productive area of about 16,000 acres. Timber for charcoal and building purposes is abundant and in close proximity to the chief mines and smelters. In most cases, however, the roads must be graded along the base of the mountains to permit supplies to be brought to market.

Lane Lectures.

The second course of popular lectures at Cooper Medical College, corner Sacramento and Webster streets, San Francisco, will be delivered during the coming winter, according to the programme below. These lectures are free. No ticket of admission is required:

Programme of Lectures.—January 4, 1884, Professor C. Cushing, "The Influence of the Mind on the Body;" January 18, Professor H. Gibbons, Sr., "The Influence of the Body on the Mind;" February 1, Professor J. H. Wythe, "Diseases of Modern Civilization;" February 15, Professor C. N. Elinwood, "Progress in Medicine;" March 7, Professor J. O. Hirschfelder, "The Spinal Cord, with Experiments;" March 21, Professor W. D. Johnston, "Spectrum Analysis;" April 4, Professor Henry Gibbons, Jr., "Sleep and Sleeplessness;" April 18, Doctor J. F. Morse, "The Anesthetic Method;" May 2, Professor A. Birkan, "The Voice;" May 16, Professor L. C. Lane, "Food." The lectures are at 8 o'clock p. m.

Metallurgy and Ores.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jacketed, either Wrought or Cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Grant and Old Abe Co. Black also Corliss Pumping Engines, 28x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Bolts for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. of every form, made of Fine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Duc's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weighs 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

HYDRAULIC GRAVEL ELEVATORS.

The Great Problem of Shallow Hydraulic Mining Solved.

NEW FIELDS OF ENTERPRISE IN HYDRAULIC MINING OPENED UP.

These machines are thoroughly effective for working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon.

At the property of the Yreka Creek Gold Mining Company, in Siskiyou county, Cal., an Elevator of the Improved Form has been introduced, which, with a head or pressure of water of 266 feet, is elevating through an 18-inch machine to a vertical height of 46 feet from bedrock to upper flume.

Descriptive Catalogues and prices furnished on application to the undersigned, who are the sole manufacturers of these machines.

JOSHUA HENDY MACHINE WORKS,

49 and 51 Fremont St., - - - - - San Francisco, Cal.

The California Perforating Screen Co.

All kinds of Quartz Screens, slot or round holes; zinc, copper and brass for flour and other mills. BOWK & WAGNER, 123 and 125 Beale St., S. F.

This paper is printed with Ink Manufactured by Charles Enou Johnson & Co., 509 South 10th St., Philadelphia. Branch Offices—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

THE FRUE CONCENTRATOR.—A new departure has been made by Adams & Carter, manufacturers of the Frue concentrator. From this time on the price of these machines will be \$575 instead of \$750, which is a very material reduction that ought to bring this excellent machine within the reach of all. Over 800 of these machines are now in use, 500 of them on this coast. The main objection to this concentrator has been its price, but that being removed, no doubt it will be even more largely introduced. It ought certainly to be worth the money asked for it to-day in view of the work it is able to accomplish. Concentration is now much more generally resorted to than formerly, and many mines can be made to pay where the ores are crushed by this means, that would not pay without it.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with
Hulls of Wood, Iron or Composite.ORDINARY ENGINES compounded when ad-
visable.STEAM LAUNCHES, Barges and Steam Tugs con-
structed with reference to the Trade in which they are
to be employed. Speed, tonnage and draft of water
guaranteed.STEAM BOILERS. Particular attention given to
the quality of the material and workmanship, and none
but first-class work produced.SUGAR MILLS AND SUGAR-MAKING
MACHINERY made after the most approved plans
Also, all Boiler Iron Work connected therewith.WATER PIPE, of Boiler or Sheet Iron, of any size
made in suitable lengths for connecting together, or
sheets rolled, punched, and packed for shipment ready
to be riveted on the ground.HYDRAULIC RIVETING. Boiler Work and
Water Pipe made by this establishment, riveted by
Hydraulic Riveting Machinery, that quality of work
being far superior to hand work.SHIP WORK. Ship and Steam Capetans, Steam
Winches, Air and Circulating Pumps, made after the
most approved plans.PUMPS. Direct Acting Pumps, for Irrigation or City
Water Works purposes, built with the celebrated Davy
Valve Motion, superior to any other Pump.

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace
many features that are entirely new and of great practi-
cal utility, which are covered by letters patent.No other furnaces can compare with these for dura-
bility and in capacity for uninterrupted work.
MORE THAN ONE HUNDRED of them are now run-
ning on the Pacific Coast, giving results never before
obtained as regards continuous running, economy of
fuel, grade and quality of hullion produced. We are
prepared to demonstrate by facts the claims here made.These Smelters are shipped in a complete state, requir-
ing no brick or stone work, except that for the crucible,
thus saving great expense and loss of time in construction.Complete smelting plants made to order of any capacity
and with all the improvements that experience has sug-
gested as valuable in this class of machinery. Skilled and
experienced smelters furnished when desired to a open
intend construction and running of furnaces. Estimates
given upon application. Send for circular.

RANKIN, BRAYTON & CO.,

Pacific Iron Works, San Francisco, Chicago
and New York.

MINERS' HORSE WHIM.

ONE HORSE CAN EASILY HOIST OVER 1,000 LBS.
at a depth of 500 feet. The Whim is mainly built of
wrought iron. The hoisting-drum is thrown out of gear
by the lever, while the load is held in place with a brake
by the man tending the bucket. The standard of the
whim is bolted to bed-timbers, thus avoiding all frame-
work. When required, these whims are made in sections
to pack on mules.

120 in Actual Use.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

A Horse Power Hoisting Machine.

Among the more modern conveniences for the miner and prospector are the horse power hoisting machines, which are simpler in construction than the old fashioned horse-whim, and a long way ahead of the old hand windlass so common everywhere. We illustrate an improved form of horse power hoist, showing it placed for operation. It is designed for mining purposes or raising coal or water out of a shaft. It will raise a bucket or weight weighing from 500 to 700 pounds, 60 to 70 feet per minute. The machine is made entirely of iron and steel excepting the sills, and is not affected by dry or wet climates. The hoisting drum is under complete control of the man at the shaft, landing the bucket by operating the levers at hand, and by which means the drum can be thrown in and out of gear at will when the horse is in motion, or the bucket lowered by the brakes as safely and conveniently as by a steam power hoist. There are no clutches to throw out or in gear. The drum will carry 500 feet or more of $\frac{3}{4}$ inch steel wire rope. The machine is small, light, easily handled and durable, sufficiently strong to do the desired work, and so simple that it can be readily understood by any miner or person inexperienced with machinery. There is a safety attachment on the end of the drum in case of an accident, the dog always being in gear when the bucket is being raised. The agents for this coast, Messrs Parke & Lacy, No. 21 and 23 Fremont street, in this city, give the following directions for placing and working this machine, which at the same time shows its methods of operation.

Place the machine in position so that the center of the drum is opposite and at right angles with the sheaves on the gallows frame or tripod; dig small trenches six or eight inches deep to receive cross sills and cast bridge tree, and then stake or weigh down securely. Bolt on the shifting rods, and after obtaining distance, dig a trench and put down sufficiently deep; then fasten down securely a piece of timber; bolt down on the timber the casting to receive the shifting levers, and lower sheave, and place a plank or timber on each side of the levers and rope, bridging over for horses to pass. A gallows frame or tripod, whichever will be the most convenient for the place where the ma-

chine is to be worked, should then be put up, using two or more sheaves.

In working the machine, when the weight is raised high enough the brake lever is applied; then throw out the gear wheels by moving forward the gear lever; when the weight is lowered throw the wheels in gear, which will keep the weight any desired height. In working the power a breeching harness should be used, as is shown in the cut. Extra care should be taken to have the gear wheels kept close in gear, for if they are allowed to work open there is danger of breaking the teeth. To put the crown wheels closer in gear, tighten two nuts connected with the iron bridge tree, loosen the set-screw in the adjustable collar on the outer end of the drum, and turn the collar to the left until the wheels are close in gear; then tighten up the set-screw. To take up slack rope use the

machinery without great expense; so whatever is wanted is mostly transported in the summer. Since the extension of the railroad system to the south a wider market has opened for our machinery, which has, by the way, an excellent reputation for strength, design and durability. Arizona, New Mexico, and Mexico are supplied mainly from here. To the north, also, our machinery goes, and Oregon, Idaho and Montana have many examples of the work of the San Francisco mechanics.

The quartz mill machinery and appliances made by our local foundries and machine shops is noted for its strength and its perfect adaptation to the work to be done. They have had so many years experience in this kind of work that faulty designs, shapes or sizes have been eliminated, and only those which have stood the test of actual work satisfactorily are used.

Be Hopeful.

Although the result of the mining debris litigation is calculated to make the hydraulic miners despondent, there is no reason to give up hope entirely, and to think that California mining is going to ruin. There are hundreds of quartz mines being worked where good miners may find employment. In fact, it is probable that an impetus will be given to quartz mining, because so many miners will want to engage in it. There are fields for the prospector in the southern part of the State, and the finding of one good mine often leads to the finding of others.

There are drift miners at work too, and no doubt there will be many more. The owners of hydraulic mines that have any specially rich strata, will work them by drifting, if they are

not allowed to hydraulic their whole deposit. And drift mines employ more men than those worked by the nozzle and the stream.

Quartz and drift mines will develop activity in many places. The men who are thrown out of work now, instead of idly bemoaning what might have been, should accept the fiat and do the next best thing. It is hard, of course, to have homes broken up and business disturbed. But it will do little good to despond. The effects of the decision are far-reaching, and

AN IMPROVED HORSE POWER HOISTING MACHINE FOR MINERS' USE.

crank on end of the drum. Should it not be convenient to place a whim close to the shaft, two extra levers and a casting can be furnished, and put on if required.

The dimensions and weight of the hoisting power are as follows: Drum, 22 inches long by 21 inches in diameter; bed frame, 5 feet 3 inches by 2 feet 9 inches in width; height, 10 inches; weight, 1,200 pounds.

Mining Machinery.

Just at this season of the year business at the foundries is apt to be dull, and no exception to the rule is apparent this year. There are few large jobs in hand at our local works. Of course all of them have more or less in the shops, but little very extensive work is being done. So much of the machinery made by our foundries is of the class of mining or metallurgical appliances, that when the mines are not active the foundries are not. So many mines are situated in mountainous regions that during the winter months it is impracticable to move

There is no better quartz crushing machinery in the world than a California mill. The pumping appliances in vogue are also made strong and durable, and are so constructed that the very best results are accomplished. The hoisting works of different kinds and patterns are solid, simple and admirably adapted for constant and safe use.

We have become noted of late for our furnaces for smelting lead and copper; and the ore-roasting furnace has reached perfection on this coast. As to the appliances of mining, such as cars, cages, buckets and all the dozens of things required, purchasers may be sure to get perfect types here. In fact, mining machinery of all kinds can be procured in this center, there being many agencies here for the sale of those articles not made here, and those made for the California trade are generally of the best class.

Ice in New York has floated up East river on Sunday and formed under the Brooklyn bridge, making a complete bridge between the two cities, the first time since 1875.

many only remotely connected with the industry affected will feel the result more or less. In a country like this, with a good climate, wonderful undeveloped resources, plenty of mines, and a great area, even the most unfortunate have much to look forward to. California is by no means played out. She yet retains the first place on the list of gold producers of the world, and the second in the total bullion product. Her mines are not all worked out; her forests are abundant, her fields are broad and fertile. The dwellers within her borders who cannot do one thing can do another. There is plenty for the willing hands to do. Many of the natural resources of the country are only partially developed. Men and muscle are wanted to bring them out. No one is going to starve in the midst of our plenty. It is better to look on the bright side of the subject and be hopeful, taking up whatever comes to hand, with the idea of bettering the condition by the means most available. While awaiting the final decision we can work as well as wait.

CORRESPONDENCE.

Saving Gold.

EDITORS PRESS:—In looking over the last report of the Director of the Mint, upon the statistics of the production of the precious metals, kindly sent me by Horatio C. Buchard, Esq., of Washington, D. C., I must say I was confronted by the extravagant losses entailed by the present old system of wet crushing (gold), stamp mortar and copper-plate amalgamation. This system I have been opposed to for many years, but it is dangerous for any Superintendent to scout at the present old method, for it would be at once thought that he wished to try some personal hobby of his own. But in the name of common sense let us have a fair discussion on this subject in a broad light, that all may be benefited; for it is too well known that by the old system of amalgamation, gold ores in the stamp mortars (more especially when the gold is fine) with quicksilver, causes flouing and granulation of this metal in the process of trituration. These minute globules of mercury become coated with impurities, causing a percentage of floured gold. The power of cohesion is lost, and while in this condition without the aid of settlers and chemicals, it is impossible to bring the mercury together in a mass, so that it passes away in the slimes. This is the main cause of the loss. By referring to the statistics I found that one of the oldest and best mining authorities, Mr. A. B. Paul, says: "We are not working to save gold but to crush rock. Our present general system of gold mining and milling is based upon the idea that gold is mainly coarse; while examination will show that the higher percentage is in atoms finer than flour itself. In my experiments gold has been taken up so fine that in distilled water it would not precipitate in less than five to ten minutes. [I can vouch myself for this statement.] Can you save this kind of gold by running water down stream? Again, can you obtain gold of this kind without minute reduction? Herein lies the secret of high assays before working, and small returns after."

Mr. Deetken, of Grass Valley, California, in order to determine the loss of gold by mill process tabulates a series of assays made of the tailings of ore from the best mills in the State, which shows the loss to have been 40 per cent. of the yield, of which the float loss was nearly 14 per cent. Fossett's table of seven years' work in Colorado shows an average value of the ore by assay to be \$37.97 per ton. The average value per ton saved by milling and smelting was \$14.50, showing a loss of \$23.47 per ton in gold and silver, or more than 60 per cent. Again, in the London *Quarterly Journal of Science*, in an article on the subject, it was stated that the gold caught on plates is, under the most favorable circumstances, only 40 per cent. of the assay value of the ore. Prof. Raymond has said, in a former report, that it is impossible to state accurately what percentage of gold is lost in milling; but that a very large amount is lost cannot be doubted. This loss probably varies from 30 to 70 per cent, according to the nature of the gold ore. "Fossett's Colorado," page 292: "It is estimated that more gold has been wasted in milling and has been washed down the creeks and gulches than has been saved." Then again, Albert Reichenbecker, a graduate of the German schools, an acknowledged authority in mining matters, says: "The proportion of gold saved on the plates and aprons varies in a well constructed mill between thirty and fifty per cent of the whole amount of gold in quartz, and may average forty per cent." Then again, Prof. Eggleston estimates the loss of between fifty and sixty per cent of the total yield of the ore.

I could cite numerous others on this question. Suffice it to say, however, that the best regulated mills lose a great deal in this age of scientific advancement which should not be lost. Some mill men advocate fine screens, say No. 60. My experience is that the loss is greater by reducing in stamp mortars the ore to such fineness, for the gold and mercury then become more floured, and pass off in the slimes, thereby increasing the loss, which no copper plates will catch, even if electro-plated with silver or gold.

I have given practical attention to the reduction of gold ores for the past thirty years, and find myself following the old system with very few improvements, but not as a matter of choice. It is so hard to introduce anything new, prejudice going always against one. I hardly dare to adopt a plan that is far surer and safer, because it would be at once considered a "hobby." So let us unite, exchange ideas, and see what can be done to lessen the evil. The matter must be faced, and I feel sure can be successfully combated. We have tried the old system long enough. Of course there are legions of patented mills, concentrators, amalgamators, etc., but so far what do they amount to if there is no general system pronounced by trial of time, and in all conditions, to be perfect?

My idea of the matter I will suggest in a very few words. Crush your ore coarse enough not to bruise up your sulphurets too fine, so that they may be readily caught, say by a true concentrator, which is as good a machine as is made for my purpose. First of all, the most important point, do away entirely with stamp mortar amalgamation. After the base metals

have been saved by concentration pass the residue through pans, and there amalgamate. I prefer my own pans, as they are self-discharging. They grind and amalgamate perfectly, and do not flout the mercury, reducing the pulp to thin paste. Then let the overflow or slimes pass into wooden settlers with revolving agitators; then, by careful manipulation, at least ninety per cent will be saved.

I am, from what little I know of Morris' system, inclined to think well of his process; but he must demonstrate by actual working tests of large quantities, that his method is what it claims to be. There can be no better moment than at present—when we have to face known losses by the old system. It is not too much, perhaps, for me to say that our mill is as perfect a gold saver as the old appliances permit. From assays made I am not losing a very great percentage, but there is no reason why that loss may not be saved. I trust the remarks I have made will be taken up by others, and their opinions fully expressed with the one object in view of a common good. I have lately visited all the principal mills in Calaveras and Amador counties, and failed to find anything but the old system in vogue.

W. F. DRAKE, Superintendent.

Patterson Mine, Tuttle town, Tuolumne Co., Cal.

Prehistoric Animal Remains.

EDITORS PRESS:—For several years I have been of the opinion that a one horned herbiferous animal existed in remote antiquity, or more probably before antiquity began, of such gigantic proportions that the elephant, or even the mastodon, were pigmies in comparison. Some years ago the fore leg bone of a monster animal was unearthed at Lagrange, in this county, from a hydraulic mine. It was nearly three feet in length, about three in circumference at the knee and near two feet at the smallest end. I believe it was sent to San Francisco.

A few years after the discovery of the bone, an individual exhibited an ivory tusk, or more properly a horn, on Dry creek, about eleven miles southeast of the town of Oakdale. The finder succeeded in unearthing between ten and eleven feet of the horn. It was forty-five inches at the large end in circumference, and nine inches in diameter at the small end. Both ends were evidently broken off. The horn was much decayed and had crumbled away to a great extent and must have been a great deal larger and longer when the animal carried it.

A few years after the finding of this horn, a son of Dr. Booth, of Oakdale, discovered, about two and a half miles west of where the large horn was dug up, on a branch of Dry creek, the baby of the large animal who sported the large horn. The bones were embedded in a coarse hardpan, and the water of the creek had washed the vegetable matter, or mold, and gravel away, leaving the head and most of the fore-quarters of the animal exposed to view. The head was downstream. Its shape, formation and size could be plainly discerned, and the position of the horn, in reference to the nasal bones, was well defined. The horn was attached to the head about eighteen inches above the end of the nose, and was about five inches in diameter where it started out. I succeeded in unearthing four feet of it, to where it entered a conglomerate strata, but it soon crumbled into small pieces. The head resembled the rhinoceros more than the elephant. It had not the vaulted and cellular skull of the latter animal. In size the head was much larger than a half barrel, and considerably longer (it was actually much larger than I describe it). The lower jaw was gone, but four molars, two large and two small, were left. The larger ones were five by six inches on the surface. The enamel was as bright and perfect as when the animal was living. The smaller were evidently of no use to the animal. They appeared to have been inserted about five inches in the jaw. The fore leg bones were twenty inches long. I have one of the molar teeth in my possession now, and some of the fragments of the bones. The large horn first mentioned would weigh in the life of the animal fully 150 pounds.

I have no doubt that this huge monster was a distinct species never before discovered or described. The facts I have briefly attempted to give can be verified by a number of witnesses. The large horn was taken to Stockton, where little attention was paid to it, and the finder was accidentally killed. What became of it I am unable to state.

L. M. B.

Oakdale, Cal.

Response to Mr. Bowles.

EDITORS PRESS:—I think there can be no doubt that Mr. Bowles is right and I was wrong as to the precipitation of gold from a solution of the tetrachloride by manganese protochloride. The idea must have arisen from the general truth that the lower chlorides of metals which can form higher chlorides, do precipitate gold. Possibly manganese protochloride may do it at a very low temperature, I have not time to try it. Score "1" for Bowles, and now for the other charge.

To "back" against Fresenius would require some courage; but when Fresenius and fact are both arrayed against one marshaled by so gallant a young officer as Mr. Bowles, what can one do but surrender at discretion. But *festina lente*; poco a poco anda lejos; regards de plus pres. Let us see if we had formally occupied the position which is so vigorously assaulted,

or whether we had only a *corps d'observation* stationed there for precautionary purposes.

The article referred to by Mr. Bowles is not at hand; but from his quotation it appears that I said "it seems possible," etc., the apparent possibility being suggested by the previously stated fact that copper sulphide is oxidized into sulphate by contact with gold perchloride. Having made one mistake through a want of caution, I may surely be permitted thus to guard against another. It may be that the gold in the mixed solution is all precipitated first, but if it is not, and we stop short of saturation of the leach with hydrogen sulphide, I see no reason why metallic gold and copper sulphate might not be produced. I must again plead want of time for experiment, but I am not aware of any law compelling us to saturate our liquor with H. S. And I think it might be "readily seen that gold in the presence of a copper salt may be precipitated in metallic state" by means of hydrogen sulphide, simply thus: By using copper sulphide to throw the gold down, said copper sulphide being produced and reproduced by means of hydrogen sulphide.

Prescott, A. T.

C. H. AARON.

Mineral or Agricultural Lands.

Following is the text of a recent ruling of the Commissioner-General of the Land Office, relating to agricultural and mineral lands in Santa Clara county. It will be seen that the land office at Washington sustains the decision of the Register and Receiver of the San Francisco District:

DECEMBER 18, 1883.

Register and Receiver, San Francisco, Cal.—GENTLEMEN: In the matter of the Santa Clara Mining Association of Baltimore vs. Giacomo Scursur, B. Scursur and Michael Sadielovich et al., being a contest to determine whether certain portions of Sections 30 and 31, Township 8 S., range 1 E., of Sections 25 and 36, Township 8 S., range 1 W., and of Section 1, Township 9 S., range 1 W., are more valuable for minerals or as agricultural land, before me on appeal from your decision of April 30, 1883, holding the land in question more valuable for minerals, the evidence has been carefully considered. It would appear from the record in the absence of all showing to the contrary, that due notice was given to all parties. Said evidence is voluminous, comprising about 800 pages of testimony, besides maps, diagrams, photographic views, etc., and is largely corroborative and cumulative.

The lands which are the subject of controversy aggregate 957.32 acres, lying in Santa Clara county, California, within sixty miles of San Francisco and near the city of San Jose. They are in the form of a peninsula lying between Capitancillos creek and a branch thereof, and contiguous on the north and east to the Guadalupe Quicksilver mine, the property of the above association, and one among the largest and most valuable of its kind in the world. From the confluence of said streams on the north, the lands extend southward, a mountainous region of ridges, ravines and canyons, becoming very wild and rough towards the southern and western extremities. This general description is based upon the testimony of both parties.

The official field notes or survey of the townships containing such lands, approved March 24, 1880, described them in general terms as "very rough third rate" with some "liveoak, hickory, oak and very dense brush and chaparral." The witnesses on the part of the mineral claimants are assayers, mining surveyors and engineers, mining experts, the township assessor, practical miners and the neighboring farmers; on the part of the agricultural claimants, neighboring farmers, claimants and others, nearly all of whom are without experience in mining, and none claiming expert knowledge of minerals or mining. The evidence for the mineral claimants shows that within a distance of four miles lie the New Almaden, Henriquita and Guadalupe quicksilver mines, all valuable and extensively worked properties, the first named being the second in size and value in the world; that the lands in question are between the Guadalupe and Henriquita, the latter being about two miles from the former, the New Almaden, lying still beyond in the same line; that ore valued at \$1,500,000 has been taken from the Guadalupe mine, that several tunnels from said Guadalupe mine into the lands in question, two of them to a distance of several hundred feet each, that ore to the value of \$100,000 has been mined from these several tunnels within the limits of said land, and an equal amount expended therein in mining operations; that said land lies in a mineral belt directly in the trend of a noted mineral formation; that three distinct lodes of mineral enter said lands; that the outcroppings of these lodes are in many places bold and strong, and afford specimens of mineral-bearing rock of the same nature as those found on the surface of the mines aforesaid; that, although cultivation of small areas within said land has been several times attempted during the past twenty years, such attempts have been from time to time abandoned, and that said lands possess no material value aside from their value as mineral lands, for which they are very valuable. The testimony on behalf of the agricultural claimants is to the effect that the lands in question, though quite rough and broken, contain many lots that can be cultivated profitably, especially by devoting

them to vine and fruit culture; that various small lots are now cultivated, crops have been grown and parties are resident thereon; that any considerable workings on said land are of recent origin, and occupy but a small portion of said land adjacent to the Guadalupe mine, and that these lands are more valuable for agricultural than mining purposes. It is urged on the part of the parties last named that the fact that, with the exception above noted, no portions of said lands have been profitably mined, or during recent years attempted to be mined, being at the same time near to the great cities in a county where mining has for years been a chief occupation and resource of the people, should be proof conclusive that said lands are not valuable for minerals; but, giving the argument its full weight, a similar one, it seems to me, will, under the circumstances of the case, apply with equal force to controvert the claim that these lands have any considerable value for agricultural purposes.

The association and its predecessors in interest have been extensively mining for many years in the Guadalupe mine, to which these lands have been regarded as an adjunct. A company can not be called upon to work several portions of its claims at the same time. The Township Assessor, corroborated by many parties, testifies that said lands are very poor, have no value from a farmer's standpoint except for grazing, and that two-thirds of the land would be dear at \$1 per acre. The agricultural claimants uniformly place the value of the uncleared land at \$30 per acre for agricultural purposes. The general topography of the tract in question, even in a region where farming lands are very valuable, is almost conclusive against any such valuation as last named.

There can be no reasonable doubt, I think, from the evidence before me, that three large and well defined mineral ledges enter said lands, and the presumption that they continue within and may be profitably mined, making with their spurs and connections the said lands much more valuable for mineral than for agricultural purposes, is too strong to allow the agricultural claimants, under the law, to prevail. Your decision is accordingly affirmed and you will hold said lands subject to the provisions of the mining laws.

Please notify the parties in interest, allow the usual time for appeal, and report further as circumstances may require. Very respectfully,
N. C. McFARLAND, Commissioner.

Winter in the Cœur D'Alenes.

J. B. Carpenter gave to a *Helena Herald* reporter some interesting items from the Cœur D'Alene mines he had recently left. Eagle City is the center and local point of the diggings. It has 20 cabins, put up during the autumn months. November and December have been in the main stormy months, and such a thing as getting out and in has been to many a desperate undertaking. At Pritchard Creek camp the snow for weeks has been deep, and it has been next to impossible to get out logs or building material of any kind. The trail to and from the mines at this time is dangerous, and within the past 60 days numbers of lives of men and horses have been sacrificed to cold and snow, and the river fords and quicksand encountered on the way. Of the several hundred fortune hunters who reached Pritchard creek during the fall, not to exceed 100 remains to be wintered there. For the few only who are now there is subsistence sure and shelter sufficient. Communication with points on the lake and railroad is too precarious for any considerable number to think of wintering this year in the mines. The matter of supplies is the serious drawback, and in this particular no considerable relief can be expected till well along in the spring months. At Eagle City flour is worth 20 cents per pound; bacon, 40 cents; sugar, 75; beans, 40; butter, \$1.50; beef and venison, 25, with little to be had, and other necessities scarce and correspondingly high.

Mr. Carpenter is enthusiastic as to the future of the Cœur d'Alene section, to which he intends to return in the spring. It is a great mineral country, abounding not only in placers, but in gold and silver ores. He has with him specimens of free gold-bearing quartz and samples of galena ore, all taken from the mountains bordering on Pritchard creek. He also shows nearly two ounces of coarse gold washed from what is known as the Widow's claim—an average exhibit worth about \$18 an ounce. The heaviest piece in the collection weighs \$3; but from the same ground, he states, have come very large nuggets; one weighs \$300. Mr. Carpenter is confident that another year will see a big placer camp producing immense treasure in the Pritchard creek section.

THERE are whole mountains of ore in Eureka district that are not profitable to reduce by smelting, but which would yield handsome fortunes if treated by milling process. It has already been amply proved that there are mines out of number, not only here, but in adjoining districts, which would give splendid returns to capitalists who would purchase them and erect mills for the treatment of the ores. Milling business alone, independent of mine owning, would prove an immensely profitable enterprise.

J. C. PLUNKET, Esq., who makes a specialty of mining law, is now well located in the new building on the north-east corner of Broadway, Oakland.

MECHANICAL PROGRESS.

Brazing Band Saws.

There appears to be a growing fashion for brazing band saws with glass blowpipes, and as a maker I am continually being asked for apparatus for this purpose. It is not possible to reply privately to all, and no doubt some information on this point will be useful to your readers. If gas is once used to braze a band saw, its use is continued as a matter of convenience, and after a short time breakages gradually increase in number. As these do not occur exactly at the joint, no blame is attached to the use of gas, and the cause of continual failures is rarely if ever discovered. It is well known that a gas flame not only scales steel deeply, but also destroys the nature by burning the carbon out, and this occurs specially at the edge of the flame. Band saws brazed by gas almost invariably break again at a point some little distance from the previous fracture, at a point where the outer edge of the flame has damaged the metal. A large proportion of the users seem to be completely puzzled as to the method of repairing easily. The only really satisfactory way is to make a thick, heavy pair of tongs red hot and clamp the joint with them. The heat melts the spelter instantly, and makes a good joint without scaling or damaging the steel. For a joint which has to stand constant heavy strains and bending, it is better to use an alloy of equal parts of coin silver and copper, melted together and rolled out thin. This alloy never burns, cannot be overheated, and makes first-rate joints which will stand hammering and bending to almost any extent.—*Engineering.*

POLE RAILROADS appear to be coming into quite extensive service in some parts of the country, as is shown by the fact that a manufactory has been established at Nashville, Tenn., for "pole road locomotives." This locomotive, which was invented by Mr. W. K. Cole, of Montgomery, Ala., about a year ago, is furnished with grooved wheels to be run on wooden poles, instead of metallic track. It is similar in appearance to the locomotives in use on narrow gauge roads. The Nashville American says of the invention: "The pole road is wonderfully cheap, and is especially adapted for hauling in the lumber regions. The track is not a permanent one, the poles being merely fastened down with wooden pegs. Ten miles can be laid down in one direction in one day, and taken up and laid in another direction the next. The engines, which will be made by the new company, will be capable of pulling up a grade of 400 feet to the mile about four times what an ordinary freight or passenger engine is capable of. The convenience of an engine and road of this kind for use for hauling timber in mountainous regions is obvious. The wheels are so arranged as to have a lateral play of eight inches, thus being adaptable to either a broad or narrow-gauge road. To admit of this play-chains are used instead of rods as drivers. An average speed of fifteen miles per hour can be obtained."

WONDERFUL INVENTION IN TELEGRAPHY.—There has recently been perfected, after some three years of patient study and investigation, an invention that bids fair to revolutionize the present method of telegraphic transmission of dispatches. It is called the Synchronous Multiplex System of Telegraphy, and the inventor is Mr. Patrick B. Delany, of New York. Briefly stated, the result of Mr. Delany's discovery is to enable numerous telegraphic dispatches to be simultaneously transmitted over one telegraph wire. Hitherto, the greatest number that could be so sent was limited to four, as in the well known quadruplex system, but in the synchronous-multiplex system the division of a single line has been carried as far as seventy-two, and the limit in this direction does not yet appear to have been reached. The value of the discovery will by no means be diminished when it is known that in the synchronism system, unlike the quadruplex system, these messages can be sent either all in the same direction, or any number in one direction, and the remainder in the opposite direction.

AN INTERESTING DISCOVERY.—Prof. Calvert has recently made the interesting discovery by practical tests that the carbonates of potash and soda possess the same property of protecting iron and steel from rust as do those alkalies in a caustic state. Thus it is found that if an iron blade be immersed in a solution of either of the above carbonates, it exercises so protective an action that that portion of the iron which is exposed to the influence of the damp atmospheric air does not oxidize, even after so extended a period as two years. Similar results, it appears, have also been obtained with sea water, on adding to the same the carbonates of potash or soda in suitable proportion.

A COTTON PICKING MACHINE.—The first bale of cotton ever picked from a field by machinery was exhibited Oct. 30, 1883, at the Charleston Cotton Exchange, and attracted general attention. The condition of the cotton is pronounced by cotton men to be as good as the hand-picked. The cotton has the same grade. What a world of thought, anxiety and wealth has been expended to secure the above noted result, and what a change it will produce in the agricultural labor of the South. It is to the cotton planter

of the South what the grain reaper is to the farmer of the North and West. The mechanical cotton picker will not stoiko or go off to camp-meeting when the crop is ready for harvest, but will take the place of thousands of too often indolent colored laborers. It will in the end prove a blessing to the colored people of the South, for they will be compelled to seek other channels of labor which will require of them greater cultivation and use of their mental faculties.

A NEW USE FOR MILD STEEL.—An English exchange says: "Attention is being drawn to the use of mild cast steel for stern-frames, rudders, etc. The steamer Euripides, now in a Liverpool graving dock, after running on a reef of bowlders, is found to have sustained no damage to her stern or stern-frame, except that there are indentations in the material. The stern is unaltered in shape. The cause is to be found in the fact that there was no weld, the structure being in each case one piece of solid cast steel. Competent judges believe that the solid mild steel stern saved the vessel from loss. It is stated the licensee for the make of these articles can sell the new solid articles cheaper than the old fashioned riveted ones."

A NEW NAIL MACHINE.—A new self-feeding attachment for nail machines, in experimental use at Brown, Bonnell & Co.'s works, Youngstown, Ohio, is well spoken of. It is claimed that it is capable of feeding a plate of any size used in the manufacture of nails, and that it is a clean and true feeder, as shown in ten hours' work a few days since, when the machine to which it was attached cut twelve kegs of seven-penny nails. It is stated that other machines in the works will be supplied with this feeder as soon as the feeders can be furnished. They cost \$80 each. The inventor is Mr. J. H. Dunbar, machinist at the works mentioned.

FRICTION.—Professor Thurston states that the co-efficient of friction of lubricated surfaces under pressure, as given in text books, are much too high; instead of 4 to 7 per cent, as generally stated, he has obtained as low as one-fourth of 1 per cent with sperm oil. This, he says, is the best he ever found for heavy pressures, and he has made experiments all the way from very light up to 1,500 pounds per inch of surface. The crank pins of beam engines on steamboats, where 1,000 pounds pressure to the square inch is not uncommon, run as low as one-half of 1 per cent for the friction.

INCREASING THE POWER OF A BELT.—The usual ways of adding to the transmitting power of belts are by applying to them oil, rosin or some adhesive substance, and by tightening them on the pulleys. The use of oil, rosin, etc., results in a direct waste of power, for as it gets old it becomes gummy, and the belt sticks to the pulley, requiring a more considerable power than is generally supposed to separate it, and effectually neutralizes all the advantage sought to be gained by its use.

WOOD KNOTS. Wood knots are in great demand, to meet the increased esthetic taste of the day. They are subjected to a steaming process which softens them and develops their color, and are then used in exceptionally fine veneering. Persons who are experts in judging what knots are of value make considerable money by going about looking for them. Two were recently shipped to New York from California, in that State, which weighed respectively 1,150 and 1,490 pounds.

TESTING PLANE KNIVES.—A set of new knives should be carefully tested to see that they are correctly balanced and kept so. A knife slightly out of balance throws the cylinder out, makes rough work and wears the bearing. This, when once started, grows rapidly worse, and getting the knives back to balance does not remedy the matter. Both the spindle and boxes are brought to that state where a machinist's services are necessary to return and balance the cylinder.

BONES, BEARINGS AND JOINTS.—Crank pin boxes and main shaft bearings should be of phosphor bronze bearing metal or of good gun metal (copper and tin), or genuine Babbit. The journals should be accurately in line, and the fit should be close enough to allow the flow of oil to pass. If too tight they will heat and sweat; if too loose, they will pound and wear, and if out of line they will do all three.

A NEW HORSE SHOE.—An English mechanic has invented a horse-shoe composed of three thicknesses of cowhide compressed into a steel mold and subjected to a chemical preparation. It will last longer than the common shoe, weighs only one-fourth as much, does not split the hoofs, requires no calks, and is very elastic.

GAS ENGINES from one-fourth horse-power to 80 horse-power are now made. Medium sized gas engines, say 16 horse-power, will run on a consumption of fuel equal to 1 1-5 pounds of coal per horse-power per hour, which is about one-half the fuel required for the most economical steam engines of the largest size.

STRENGTH OF PAPER.—One of the most wonderful things about paper is its strength. As an illustration of this, a Bank of England note twisted into a kind of rope can suspend as much as 329 pounds upon one end of it and not be injured in the least.

SCIENTIFIC PROGRESS.

The Solar Atmosphere.

Professor Young, a well-known American authority, says that it seems demonstrated, as a consequence of the low mean density of the sun, and its great force of gravity, that the central portions of that body, and, in fact, all but a comparatively thin shell near the surface, must be in a gaseous condition, and the gases at so high a temperature as to remain for the most part dissociated from each other and incapable of chemical interaction. Under the influence of the great pressure and high temperature, however, their density and viscosity are probably such as to render their mechanical behavior more like that of such substances as tar or honey than that of air, as we are familiar with it. The visible surface of the sun, the photosphere, is composed of clouds formed by condensation and combination of such of the solar gases as are cooled sufficiently by their radiation into space. These clouds are suspended in the mass of uncondensed gases, like the clouds in our own atmosphere. The liquid and solid particles of which they are made up descend continually, their places being constantly supplied by fresh condensation from the ascending currents which rise between the cloud columns. From the under surface of the photosphere there must be an immense precipitation of what may be called "solar rain and snow," which descends into the gaseous core, and by the internal heat is re-evaporated, decomposed and restored to its original gaseous condition. The thickness of the photospheric shell, judging from the phenomena of the spots, can hardly be less than 10,000 miles. The weight of the cloud-shell, and the resistance offered to the descending products of condensation, act to produce on the inclosed gaseous core a constricting pressure, which forces the gases upward through the intervals between the clouds with great velocity, so that jets or blasts of heated gas continually ascend all over the sun's surface, the same material subsequently redescending in the cloud-columns, partly condensed into solid or liquid particles, and partly uncondensed. The layer of uncondensed gases which overlies the photosphere, or crust, is called the "chromosphere," the lower portion of which is rich in all the vapors and gases which enter into the sun's composition; but at a comparatively small height the denser and less permanent gases disappear, leaving in the upper regions only hydrogen and some other unidentified substances.

The dark lines of the solar spectrum originate mainly in the absorption produced by the dense gases which bathe the photospheric clouds, and these metallic vapors are only occasionally carried into the upper regions by ascending jets of unusual violence. When this occurs it is almost invariably in connection with a solar spot. The prominences are merely heated masses of the hydrogen and other chromospheric gases, carried to a considerable height by the ascending currents, and apparently floating in the "coronal atmosphere," which interpenetrates and overtops the chromosphere. As to sun spots, there can be no longer any doubt that they are cavities in the upper surface of the photosphere, and that their darkness is due simply to the absorbing action of the gases and vapors which fill them. It is also certain that very commonly, if not invariably, there is a violent uprush of hydrogen and metallic vapors all around the outer edge of the penumbra, and a considerable depression of the chromosphere over the center of the spot; probably there is also a descending current through its center. As to the cause of the spots and the interpretation of their telescopic details, he admits being unsatisfied; and as to the periodicity of the spots, he is unable to think it due to any planetary action—at least the evidence appears to be wholly insufficient as yet. The only peculiarity in his views lies, he believes, in the importance he assigns to the effects of the descending products of condensation, which, he conceives, form virtually a sort of contracting skin, producing pressure upon the gaseous mass beneath, somewhat as the film of a bubble compresses the inclosed air. To this pressure, thus produced, he ascribes mainly the eruptive phenomena of the chromosphere and prominences.

Philosophy of Creosoting Timber.

As is well known, the preservative properties of creosote are owing to its preventing the absorption of the atmosphere in any form, or under any change of temperature. It is noxious to animal or vegetable life; and it arrests all fermentation of the sap, which is one of the primary causes of dry rot and other species of decay in timber. The action of creosote—says Mr. Bale, in his work on "Saw Mills: Their Arrangement and Management"—may be thus described: When injected into a piece of wood, the creosote coagulates the albumen, thus preventing any putrefactive decomposition; and the bituminous oils enter the whole of the capillary tubes, incasing the woody fiber as with a shield and closing up the whole of the pores, so as to entirely exclude both moisture (water) and air. By using creosote, inferior porous timber and that cut at the wrong season, and therefore sappy, may be rendered durable. The Bethell system of creosoting is as follows: The timber is first thoroughly seasoned and cut to

the required dimensions. It is then placed in a wrought iron cylinder, fitted with doors that can be hermetically closed by means of wrought iron clamps. The air and moisture contained in the wood are then exhausted from it, and from the cylinder, by means of a powerful air pump. The pores of the wood being now empty, the preservation material (creosote oil) is admitted into the tank. When the wood has received all that it will after this manner, more oil is forced into it by means of hydrostatic pumps, exerting a pressure of 120 pounds to 200 pounds per square inch. This pressure is maintained until it appears that the proper quantity of creosote oil has been absorbed by the wood, which is determined by a gauge. Timber intended for railway sleepers, bridges, etc., should absorb seven pounds of oil per cubic foot; and timber required to be protected against marine insects, etc., requires at least 10 pounds of oil per cubic foot. The cost varies from 4d. to 5d. per cubic foot, according to the quantity of oil required.

WIRE FENCE TELEGRAPHING.—An experimental work has been going on for a short time along the Milwaukee and St. Paul Railroad Branch and the Brandon Branch, about thirty miles in length, the object being to determine whether or not the barbed wire of the fence on either side of the road can be utilized for telegraphic purposes. The fence wire was placed in proper condition for a sufficient distance to make a satisfactory test, the wire being run under the surface at road crossings. Superintendent of Telegraph Simpson decides that the plan is not practicable. Telegraph work can be done over the fence wire at this time, he says, but during the winter months, when huge snow banks completely cover the fence, the line would be made useless. There are thousands of miles of wire fence along the Western lines, and it has been contended that they should be utilized for this purpose.

PURITY OF THE ATMOSPHERE.—Two scientific investigators, one Swiss and the other French, have been analyzing the Alpine air. They ascertained that entirely pure air is not found until an altitude is reached of from six to thirteen thousand feet above the level of the sea. The atmosphere around the lakes below that level, however pure and beautiful apparently, was found to contain bacteria. Nevertheless, it was pure enough by comparison with that of the French capital, where the bacteria contained in a square foot of air are seven thousand times more numerous than those in the same quantity of air in one of the Swiss valleys.

CHLOROPHYLL IN ANIMALS.—Dr. Sedgwick gives a well written synopsis of the results of the more important recent studies concerning the occurrence of chlorophyll in animals, and its significance. These seem to show that the so-called "animal chlorophyll" has no actual existence, being in every case (possibly excepting Hydra and Spongilla) connected with a vegetable structure living in the tissues of the animal. This association of plant and animal, in the mutual benefits derived, is held to be somewhat different from the so-called parasitism known in lichens; but it is hard to see in what important respect the two cases differ.

OCEAN WAVES caused by earthquakes sometimes exert a tremendous momentary force upon the shores of the sea, although their geological action is small compared with the incessantly operating of the small waves. At the Lisbon earthquake of 1775, the oceanic wave had a height along the Tagus of forty feet, at Cadiz of sixty feet, and on the shores of Madeira of eighteen feet. The earthquake in 1746, in Peru, produced a wave which carried a frigate several miles inland, deluging the city of Lima at a distance of several miles from the coast.

TO AVOID PETROLEUM EXPLOSIONS.—With a view of avoiding explosions, M. Schlumberger recommends that a bottle of ammonia should be placed in each barrel of petroleum. On ignition, by accident or otherwise, the bottle would break, and the ammoniacal vapors would at once extinguish the fire. Dr. Pietra Santa proposes to apply this method to collieries liable to fire-damp. Tanks filled with ammonia would, it is said, stop the combustion, as it could not continue in an ammoniacal atmosphere.

The height and velocity of clouds have been determined in England by means of photography. Two cameras, placed about 600 feet apart, are provided with instantaneous shutters simultaneously released by electricity. The observer measures the angle of inclination of the cameras and the position of the cloud as photographed on the two plates, and from these data a trigonometric calculation gives the distance and height of a cloud with great accuracy.

CHLORINE AS PLANT FOOD.—A German exchange says that chlorine is a very important nutrient for plants. To all appearances the chloride of potassium exceeds the nitrate in nutritive value as long as the quantity does not exceed a definite limit. When there is too much of the chloride, the quantity of chlorophyll decreases, the plants ripen sooner, but the oxalic acid increases in quantity. In fact, it acts just like hydrochloric acid would.

PROFESSOR BERTELMINT maintains that the true element of carbon is as yet unknown; that it must be of a gaseous nature, and that diamond, graphite, etc., are but states of the veritable carbon.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

IOWA.—*Ledger*, Jan. 12: Some idea of the unprecedented richness of the rock obtained from this claim at Sutter Creek may be gathered when we state that the last crushing, consisting of about 20 tons, averaged \$430 per ton. The run before that, also aggregating over 20 tons, yielded at the rate of \$1,000 per ton. This was taken out at a depth of 100 feet from the surface. This splendid ore streak is not yet exhausted, and it is estimated that the rock in sight will pay \$400 per ton; how much of it there is remains to be proved. No underground work is being done at present. A substantial building is being erected over the shaft; also a patent one-horse whim, which will be sufficient for hoisting purposes until the shaft reaches a depth of 300 feet.

NOTES.—A. Guisto has commenced hydraulicizing on his gravel claim at Oneida Flat, which has been idle for months on account of scarcity of water. Tom Fullen has leased the Amador Queen quartz mine in Hunt's Gulch from J. Morgan, and is hard at work developing it. The Amador Canal Co. are putting in new tanks at the Tanner reservoir, to supply the Zeile and other mines south. I. N. Dewitt is busily engaged stripping ground on his mining claim at Murphy's Ridge. The Talisman mill was started Monday on rock from the South Spring hill. Work is progressing on the old Markly mine, on Dry creek, about five miles from town.

VOLCANO.—*Dispatch*, Jan. 12: Since the last rains business begins to look up, especially mining. They are taking very rich rock out of the south shaft of the Downs mine, and are running twenty stamps day and night. Gillick & Phillips are getting out some of the richest-looking rock that has ever been seen around this locality. They have been waiting for water to start the mill. The Canvin mine is getting out good rock. The Tunnel Co. is only running part of the time, owing to the scarcity of water.

SR. JULIEN.—There has been but little rock taken out of the St. Julien mine for several days past, as the workmen are engaged in arranging the interior of the mine so that they can work to advantage. The prospect still continues to look well, however.

QUARTZ MILL BURNED.—The quartz mill at the Stewart mine, near the West Point bridge, was destroyed by fire a week ago Sunday night. The loss is estimated at \$5,000, but it was covered by insurance to the amount of \$2,000.

NEW HOISTING WORKS.—The Seaton Mining Co. are putting up new hoisting works a short distance above their mill, near Drytown. The work is being done by Messrs. Reese and Brown, of Sutter Creek.

Calaveras.

RAILROAD FLAT.—*Chronicle*, Jan. 12: The mining interests of this place are improving. Mr. Edward Kerrigan, Supt. of the Spruce Gulch mine, and his foreman, Mr. David Ewald, arrived on the 8th inst., with a large load of hydraulic pipe from Amador Co. They receive their supply of water from Clark's ditch, and expect to have the mine in full operation in eight or ten days. The gravel prospects well, and without doubt they will have a good paying and extensive mine.

NOTES.—*Cor.*, *Chronicle*: The Machu mine, owned by Messrs. Hunter and Clark, is running, and I learn that they are taking out rich rock. The Wide West is still being worked. The Scorpion mine has shut down, but will resume operations soon. Geo. Eberhardt's mine is running in full blast.

ANGEL'S CAMP.—*Mountain Echo*, Jan. 2: Mining prospects have not been brighter in this section for many years. There are several quartz mills of greater or less degree which are kept steadily running and are paying well.

CAVE CITY.—*Cor.* of *Greenville Bulletin*, Jan. 9: Mining appears to be on the eve of quite a boom here at present; a few old mines are now running, and several new ones will be started later in the season. The Sheep Ranch mine is running 30 stamps on good ore, and the McPherson is running 8. At Angels a 40 stamp mill will be built in a few months. The new mill on the Orofino begins to loom up like a pile-driver in a fog, and under the management of a Plumasite will be ready to run in three weeks, if all goes well. Wages here are about the same as in Plumas, and men quite as plenty. There is an opening here for the investment of capital to very great advantage.

Del Norte.

BIG FLAT MINE.—*Crescent City Record*, Jan. 5: During the last heavy rains a slide occurred at the Big Flat mine, taking away the ditch for some distance, which we learn will cause a delay in the work for several weeks. There was also a slide at the Armand mine, carrying away the flume for some distance, and doing other damage to the works, the extent of which we did not learn.

EI Dorado.

NASHVILLE.—*Republican*, Jan. 10: The Nashville mine under the direction of Mr. Thomas K. Johnson, is at last in good paying condition, they having struck, at 500 level, an 18 foot ledge of good milling ore; the chimney appears to be pitching south, and the drift already in about 80 or 90 ft., shows the ledge still improving in size. The owner of the mine, Mr. Hendy, proposes to sink another hundred ft. immediately, and also talks of putting up 20 more stamps, besides those that are already running steadily. Mr. G. W. Bibbens, a mining expert from the Bay, has been in town several days and proposes to open up various mines, among them Mr. O. P. Hart's mine, situated north of the Nashville mine, and I believe on the same vein. There are parties also talking of taking hold of the Lone Star mine, the property of Mr. J. C. Heald.

MINE BONDED.—The Reid mine near Ringgold, has been bonded to some San Francisco parties, and we understand that operations will soon be commenced on it, under the management of Mr. J. J. McChesney, of San Francisco.

Fresno.

MILL CREEK.—*Cor.* of *Expositor*, Jan. 8: Vincent Moore and Russian Charlie, otherwise Charles Brown, discovered what promises to be a valuable

mine, on Hughes Creek. They are now sinking a shaft. The lode is about 12 inches in width, and shows considerable gold without the aid of glass; there has been very little prospecting done in this district as yet, and as soon as a mine or two can be developed here, we doubtless will have a paying camp. Messrs. Akers, Lewis and others will commence work on their ledges in the course of a few days. We are hoping that before six months have passed, the sound of the stamps will be heard.

Inyo.

THE MINNIETTA.—*Independent*, Jan. 12: Mr. J. J. Gunn has relocated this property, which produced \$321,000 in '77 and '78. It was the property of the Cerro Gordo Freighting Co.; but nothing has been done on it since March 23d, 1882. Mr. Gunn has a force taking out ore from one of the mines, which ore he will have worked by Frank Fitzgerald.

MODOCK.—Superintendent Fitzgerald reports the amount of ore, selected flue dust, and slag on hand as 307 tons. A force of ten men is at work, breaking from seven to nine carloads of high-grade ore daily. The furnaces will not be started until the weather opens. Mr. Fitzgerald intends to make the next the largest run since he took charge of the property.

§ CLOVER PATCH.—A new and extensive strike is reported in the Banner mine, at Clover Patch. Messrs. Nixon & Co. are engaged in putting an additional battery of five stamps in the Wild Rose mill.

A STRIKE.—Morton & Stapp have struck a rich pay-streak in the Red Rock mine, Lookout district. Average of assays of streak was \$207 in gold per ton; choice pieces, \$4,764.80 per ton in gold.

BEVERIDGE.—The Keynot arastras have been yielding splendidly in gold from the ores of the various mines owned by the Mexicans, but it is among the impossibilities to get at the exact amount. Chas. McEvoy has gone over to get his mill ready for work as soon as sufficient ore has been got on the dump for a run.

ABOUT READY.—It is stated that the new Maxim mill at Chrysopolis will be started up during the coming week. The machinery is of New York manufacture, and consists substantially of a cannon-ball quartz crusher. About 100 tons of high-grade free gold ore has been mined and hauled to the mill.

DIANA.—The Diana mill, at Benton, has been running for some time on rock from the old Neal mine, in Indian district, with favorable results.

Monro.

THE RISE IN BODIE.—The *Free Press* of Jan. 10th quotes from the S. F. *Post* as follows: "The insiders of the Bodie Con. Mining Co. now say that a point in the mine, on the 306 level, 25 ft. south and 40 ft. east of the main shaft, a vein from 18 inches to 2 ft. wide of very rich ore, averaging \$200 per ton, has been cut. They report that an upraise has been started in this ore, which was up this morning 35 ft. with rich ore in the top, and say that it belongs to the old Fortuna vein. These alleged developments extend over a period of three weeks. Seeing that the same insiders declared emphatically during this period, that there was nothing new in the mine to warrant an advance in the stock, we hardly know which story to believe."

STANDARD CON.—*Free Press*: During the week there has been extracted and sent to the mills 1423 tons of ore, from which 2680 ounces of crude bullion were received, and \$16,986 shipped to the company. Upraise No. 2 from south drift No. 2, 1000 level, has been advanced 8 ft.; total height 109 ft., showing the vein $4\frac{1}{2}$ ft. wide. North drift No. 1 is being re-timbered. North drift, 700 level, has been advanced 9 ft., and is now in 523 ft. North drift from north upraise is in 208 ft.; progress 8 ft. all in good ore. The stopes are looking well.

BODIE CON.—The work now doing west of the shaft at the 306 level is opening up some fine ore, which gives promises of being in good body. During the week there were 144,765 tons of ore hauled to the mill, and the same amount was crushed. The assay value of the pulp was \$37.10; that of the tailings was \$6.02 per ton.

BULWER CON.—North drift, 700 level, is in 523 ft.; progress 9 ft., with no change to note. West crosscut from south drift, 500 level, is in 486 ft., in very hard rock.

MOUNT GIBBS.—A prospector just from Tioga states that some of the claims at Mount Gibbs are looking remarkably well, and that there is considerable high-grade ore in sight in several of them. The Deer Lodge and Jefferson claims, owned principally by R. A. Sawyer, are good prospects. The latter shows a vein between five and six ft. wide, of very fine ore, assaying well. The former is a ten-foot vein which promises, if present appearances amount to anything, to develop into a fine property. Work on the Great Sierra tunnel is progressing as usual.

Nevada.

YOU BET.—*Transcript*, Jan. 11: The English Co. has been hoisting and crushing gravel regularly from their claims at You Bet, and the plates are said to give assurance that the dirt is paying well. A temporary delay is being experienced by some water breaking into a drift from the canyon Tuesday evening and flooding the underground workings.

DRIFTING THE ONLY THING.—Nat. Bailey of this city has returned from Little York where he has been for some time past engaged in making iron pipe for the hydraulic mining company of which S. Wheeler is Supt. Mr. Bailey says Sawyer's decision fell upon that locality like a thunderbolt. The company had at immense expense, put the mine in first-class shape for a big run, but immediately upon receipt of the decision all work was quit. It is quite likely they will try the experiment of drifting, although there is much doubt if the claim can be made to pay by that process.

Plumas.

ARGENTINE.—*Greenville Bulletin*, Jan. 9: The future of Argentine is quite encouraging. Mr. Haun has lately cut into a fine body of good ore in the Empire mine. Many years ago a tunnel was run, and a ledge struck in what was known as the Conkling mine, but the then owners were too poor to put up the necessary machinery to work the ore and the mine was abandoned. Mr. Haun located his claim on the opposite side of the ridge from the Conkling, thereby securing good water power; he then ran a tunnel and struck what he thinks to be the same ledge found in the Conkling, but at a greater depth. The ore is rich, and the ledge extensive. Mr. Haun has a mill already for work, and intends to begin crushing rock early in the spring.

ELIZABETHTOWN MINE.—Loring and Leavett put a man to work in the Elizabethtown mine cleaning up bedrock that had been worked over by Manson and Corbin. On the first day the man was at work he cleaned up \$90, on the second he got \$70. In one day from new ground \$425 were taken. The mine is doing well.

A GROUP OF MINES.—The Arcadian, Sunset, Antelope, Central, Garfield and New York mines are all near together, and all owned by different parties. The Arcadian and New York have each a mill of ten stamps capacity. All of the claims have been well prospected; from the two last named a good deal of ore has been worked with satisfactory results. If all of these claims were owned by one company, and worked under one management, a large and profitable mining property would be the result. The location is the most favorable in the district, the ledges rising up the mountain side, one above the other, so that ore could easily be run to the large mill that would crush the whole.

San Bernardino.

CALICO.—*Print*, Jan. 12: A similarity exists between this and Leadville, as the mineral there seems to lie in many instances in horizontal veins. Here it is found in both horizontal and vertical veins. One of these vertical veins has now been worked 500 ft. and still shows no sign of failing. This mine alone in a run of ten months has produced over \$400,000 in silver bullion, over half of which has been clear profit. Another mine, whose mineral deposits appear to be horizontal and known to be 300 ft. in width by more than 400 in length, and from which the ore is extracted after the manner of a stone quarry, has yielded over \$150,000, although the depth so far reached does not much exceed 20 ft.; this also is in successful operation. There is at least 300 men, miners and chloriders in the Calico mining district, busily engaged in getting out ore and developing the various properties, and the only mills available are the Oro Grande, which has turned out over \$400,000 of bullion from the King mine within the last ten months, situated 40 miles away; the mill at Hawley's station, 8 miles distant, which has shipped at least \$300,000 of bullion to San Francisco during 1883, and the Oriental mill, six miles from Calico, which has also shipped about \$200,000 in bullion in the same length of time. The accumulation of ore on the dumps is steadily going on, and another mill of 15-stamps would find constant employment, more especially if erected in the immediate vicinity of the mines. The Trojan district, 100 miles east of Calico, contains the well developed Bonanza King mine and its beautiful mill which has turned out in round numbers the modest sum of \$700,000 during the past year.

Sierra.

MARGUERITE.—*Downieville Tribune*, Jan. 10: The outlook for the Marguerite mine was never more promising than at present. With the opening out of a new level (No. 4), a fine ledge has been developed, proving conclusively that the vein is growing stronger as depth is acquired. A couple of new boilers have lately been placed in position, and the pumps were started up with the new power to-day. With the old boiler the work of sinking the shaft was necessarily slow, as it did not furnish sufficient power to keep the shaft clear of water. Above ground everything is being so arranged as to insure the working of the mine on a more economical scale than ever past season. The mill is running steadily on good paying ore. The flume which is to convey water to the turbine wheel, to be used in connection with the wire cable in furnishing motive power for the running of the hoisting and pumping machinery, is completed. The wheel and cable are to be placed in position as soon as they arrive at the mine.

FOREST CITY.—At the Wisconsin mine, work in the upraise has been discontinued for a time, owing to the bad air. This can be obviated as soon as sufficient water comes for a blast. In the meantime the men are busily engaged in repairing the tunnel and getting out timbers.

HOWLAND FLAT.—A subscriber at Howland Flat writes us that that once thriving town is but a sad reminder of its former self. The effect of the Chinese incubus is more noticeable every year. The Virginia Co. are still engaged in pushing ahead their main tunnel. Messrs. Strubel & Bettinger took a twelve ounce gold nugget out of the Blue Bank claim, at Poker Flat recently. It was sold to Dixon Brabban, of La Porte.

NEVADA.

Washoe District.

UNION CON.—*Enterprise*, Jan. 12: The main south drift on the 3,100 level is being pushed ahead as rapidly as possible. It is in dry ground. Recently its course has been changed more to the west, and it is now going directly toward the head of the drift which is coming up northward.

SIERRA NEVADA.—About 15 feet will be made this week in the upraise from the main north drift on the 2,900 level. The ground continues dry and favorable. On the 3,100 level a drill-hole was run 125 feet in a northerly direction, at which distance quartz was reached and a small flow of water was tapped. Work has been resumed in the northeast drift.

ALTA.—The work of cleaning out the main east drift on the 2,150 level is about completed, and they will now soon resume work in the face of the drift out into the ore body cut by the diamond drill previous to the flooding of the mine. The pumps are all working well and the water gives no trouble.

MEXICAN.—On the 3,100 level have completed timbering up, cutting a drain and putting in drain boxes. As soon as the connection is made in the Union Con. and an air gallery formed, prospecting operations will be resumed and may be economically prosecuted.

YELLOW JACKET.—The amount of ore extracted is limited only by the quantity that can be reduced by the mills on the Carson river. Since the late storm there has been some increase in the volume of water, but there is not yet sufficient to allow of the mills being run to their full capacity.

OPHIR.—Some streaks and stringers of favorable material are being cut in the drifts which are being driven north and south on the 150 level. On this level they are still extracting a considerable amount of ore that will pay for milling. The winze from this level down to those below is being sunk as rapidly as possible.

CROWN POINT.—As much ore is being taken out

from the old upper levels as can be handled at the mills on the river, and considerable work is being done in the way of exploring for new deposits.

GOULD AND CURRY.—The bottom of the joint Best and Belcher winze below the 2,500 level continues in material of a promising appearance. The amount of water at the bottom is not great.

COMBINATION SHAFT.—The new hydraulic pump is working splendidly, and to the entire satisfaction of all concerned. The shaft will now be sunk to the 2,800 level as rapidly as possible, at which point a station will be opened and a drift started west.

CON. VIRGINIA.—On the 2,700 level joint California winze No. 2 is going down at the rate of 12 to 15 feet per week in ground that works fairly well.

UTAH.—The northeast drift on the 1,750 level is being advanced quite rapidly in ground that works well and is of a promising appearance. This drift is passing through ground hitherto wholly unexplored.

HALE AND NORCROSS.—Excellent progress is being made in sinking the winze below the 2,700 level. No water to give any trouble is encountered. The winze will be put down to the 2,800 level as rapidly as possible.

BEST AND BELCHER.—The material encountered in the joint Gould and Curry winze below the 2,500 level, is still promising. Some water is coming in at the bottom, but it is handled without much trouble.

IMPERIAL.—The main west drift is now within a short distance of the old upper levels, which it is intended to explore and overhaul for ore.

SCORPION.—The usual progress is being made in the main west drift on the 500 level.

CALIFORNIA.—Joint Con. Virginia winze No. 2 is making good progress below the 2,700 level, in fair working ground.

ANDES.—Some low grade ore is being extracted, and prospecting continues at several points.

OVERMAN.—A small amount of ore is being taken out of the old upper levels.

UNION SHAFT.—Are still easing timbers and doing repair work at the 2,300 station.

BELCHER.—Some ore is still being extracted from the old upper levels.

Argentine District.

HARRIS MINE.—*Bodie Free Press*, of Jan. 13, gives the following from the *Virginia Chronicle*: The Argentine district, in which the Harris mine is located, was abandoned in early days on account of the "salting" of the North Ophir mine. The managers reported striking pure silver, and on the strength of the supposed discovery, the stock rose from a mere nominal sum to quite a large amount. Among the chunks of silver taken from the mine was a small piece on which was discovered an eagle and a Goddess of Liberty. This was carrying the thing too far, and the bottom dropped out of the mine and the district. Previous to this collapse there had been discovered some small gold ledges in different mines. Among the number was the Buckeye, which is but a few hundred yards from the new discovery, and produced at that time considerable ore of a high grade. There are now at least half-a-dozen different parties prospecting.

Belmont District.

BELMONT MINE.—*Courier*, Jan. 5: The following is a copy of Supr's. letter of Jan. 5: The ledge in north stope on 200 level has taken its proper position, showing $\frac{1}{4}$ ft. thick. All other stopes looking well and yielding good ore. Hoisting works running well. Mill will close down next week.

Candelaria District.

COLUMBUS CON.—*True Fissure*, Jan. 12: Since last report the usual amount of work has been done in all of the levels of the mine. The shaft has attained the depth of 40 ft. below the station on the third level. The drift from the third level station has been extended five ft., making a length of 25 ft. The ground in this drift has been and now is very hard, hence the slow progress. The drift from the bottom of the bonanza winze, running to connect with the third level station, has been extended ten ft., making a total length of about 80 ft. The drift has been running through ground favorable for working, and is in vein matter that shows streaks and bunches of very good ore.

THE DORAN MINE.—At the eastern end of Columbus Mining district is located the old Nevada mine. In former years it was worked with good returns; failing to yield sufficiently well in consideration of the then high prices of wages and supplies it was abandoned by its owners. A few years later it was relocated by R. E. Doran, of Columbus, and near whose home it is situated. Something over a year ago he incorporated it under the name of L. O. Yolo, and with the assistance of New York capital has done a great deal of work, which will soon return in the shape of dividends. Last fall Mr. Doran received from New York a Howland pulverizer. It is claimed for it that, with 20 horse power, 40 tons per day can be worked. Everything is being done in the best of workmanship; if the process is successful, of which there is no doubt, a great impetus will be giving to the mining interest of this county.

Eureka District.

THE RICHMOND.—*Sentinel*, Jan. 11: George Hopkins, Chairman of the Richmond Con. Mining Co., at their half-yearly meeting, held in London on the 19th ult., said: You will have noticed from the returns that the general furnace has been running continuously throughout the six months without any hindrance. The result of the half-year's work is a yield of 7,726 ounces of gold, 220,053 ounces of silver and 1,704 tons of lead. This yield is from two furnaces, one smelting 300 tons weekly, and the other a little under that amount, working with the refinery and smelting up the drosses from it mixed with low grade Richmond ore and some purchased ore. As regards the profits of the half year, a rough balance sheet made up to the end of the six months, and taking lead at its present very low price, shows the profit is about \$65,000. At the last half-yearly meeting, on the question of dividend I undertook to say that the Directors would, if they could see their way so to do, declare a dividend. I am happy to be able to tell the shareholders that when the board came to look into the question they were able to pay the last dividend of 5s. from the earnings of the company without in any way trespassing upon the reserve fund.

DIAMOND CITY.—*Sentinel* of Jan. 9: F. J. Mette returned yesterday from a visit to Diamond City,

and gives a flattering account of the Enterprise property. He says that the mine is looking better than ever, and that with the ore in sight he calculates that the furnace can be kept running at full blast for six months, with fair indications of plenty of ore afterwards, and an indefinite prospect for developments. There are now 65 men employed altogether in the mine and on the works. The furnace is working to a charm. Since it started up, Dec. 13th, it has stopped only once, and then but for two hours to tighten some belting. The ore carries its own flux in abundance. From 35 to 40 tons per day are reduced. The average of the bullion, Mr. Mette states, is over \$150 per ton.

NOTES.—John Steele is getting out rich ore from the Diagonal mine on Silverado mountain. John Potter has put up a whip on the Mildred shaft at Secret canyon, and is driving for ore from the 100 level. P. N. Hansen has had the assessment work done on the Secret Canyon Tunnel mines for 1883, and work on the property will be resumed when spring opens. Work by lessees has been commenced on the old surface workings of the Connolly mine, and the prospects are that it will prove to be a profitable venture. Messrs. Moran and McConnell shipped five tons of ore on Friday last to the Richmond works from the El Dorado mine, situated on the west side of Prospect mountain. The Mabel mine, Secret canyon, has been leased for one year to Messrs. McDonald and Humer. There is some ore in sight and the prospect for more is very good. Messrs. Graham, McKee & Co. are drifting towards the big break in the Page & Corwin mine in Secret canyon, occasionally meeting with small bunches of ore and encouraging prospects for rich developments. In addition to the high grade ores of Eureka and adjoining districts, the tons of low grade ore already exposed can be counted by millions, and the question is being asked daily by hundreds of worthy prospectors, "What shall we do with it?" Grif Thomas and Wm. Parry have relocated the Corliss mine, adjoining the Oregonian. It is a good property, and sufficient ore has been extracted from it to pay all the expenses of working until lately, and the prospect for making it pay again is good. The Whalen mine and other locations connected with it in Antelope district have been relocated by John McCuish and others, and it is understood that Eastern parties will become interested and develop the properties. Messrs. McNaughton and Laird are extracting about four tons of ore daily from a 12-foot breast in the Colorado mine on Prospect mountain, which they have leased. There are now 50 tons of ore being sampled at the Eureka Con. furnaces, which assays from \$120 to \$180 per ton. John McCuish has relocated the Persia, Jenny, Aldine, Roma and other mines in the Antelope district, in the interest of P. N. Hansen, himself and others. There is a good shaft on the Roma, and he is running a tunnel into the hill to connect with it. The Geddes Co. are pushing prospect work in the Geddes & Bertrand mines with Burleigh drills. It is probable, if new ore bodies are discovered, that they will prove more profitable than those already developed, as the rich ore from the latter had already been gouged out by tributaries. The sampling of nearly 25 tons, net, ore from the Silver Connor mine on Prospect mountain has just been completed at the Eureka Con. reduction works, the yield per ton from which is \$67.89 in gold and \$19.65 in silver. The Silver Connor is now as much affected by the discount on silver as other mines, for the reason that of all the ore extracted the yield is three-fourths gold. There are whole mountains of ore in Eureka district that are not profitable to reduce by the smelting, but which would yield handsome fortunes if treated by milling process. Milling business alone, independent of mine owning, would prove an immensely profitable enterprise. Grif Thomas is energetically developing the Oregonian mine on Prospect Mountain. He has completed a tunnel to a distance of 125 ft, and made connection with an incline shaft down from the surface 60 ft. He is sinking an incline winze on ore and ore indications. The winze is now down 30 ft from the tunnel level, two small veins being in sight for the entire distance. The upper one runs in value at the rate of \$500, and the lower one \$300 per ton, both of them coming nearer to each other as depth is attained, and will probably prove to have come from the same source.

Ploche District.

MENDHA.—*Record*, Jan. 5:—This mine at Highland, the property of the Day Co., is gradually growing better, and it appears nearly certain that the ore lately opened up at the 90-ft station is an extensive body. This ore has turned and passed the shaft and is now going east. The vein is nine ft in width, and the ore is of the same uniform grade and quality, and the teams keep steadily hauling ore from the mine to the furnace. The late ore struck on the other side of the shaft, some forty ft below this body, has been run upon a few feet. The ledge is now two feet in width, but we did not learn what percentage it went in silver. Work at the bottom of the shaft is being pushed ahead.

Paradise District.

WILD GOOSE.—*Silver State*, Jan. 8:—Yesterday four bars of fine bullion of the actual value of \$9,321.25, were received at the express office here from the Paradise Valley mill. This is the result of a week's run of a ten stamp mill on ores from the Wild Goose and Paradise Valley mines. This is an auspicious beginning for the new year, and indicates what Superintendent McCurdy intends doing in 1884. It is the largest bullion shipment ever made in the same length of time from the Paradise mill, and as there is plenty of ore, and the mines are being worked on legitimate principles and not for speculative purposes, their bullion product from ores reduced with ten stamps will doubtless average \$25,000 per month, and net the owners a handsome profit.

Tuscarora District.

ARGENTA.—*Times Review*, Jan. 10:—South crosscut is in 44 feet, progress for the week, 6 feet. Rock is very hard again.

NORTH BELLE ISLE.—East crosscut 300 level, total distance 64 ft through very hard formation showing signs of rich ore.

BELLE ISLE.—The north drift, 450 level has been advanced 16 ft during the past week.

INDEPENDENCE.—The usual progress has been made in the drifts and crosscuts. The past week shows no change to mention.

CENTRAL CON.—Shaft 150 ft, sump 10 ft, station

cut out and timbered north drift 8 ft. Rock hard and full of iron—good working ground.

GRAND PRIZE.—South drift on the 500 level has been extended 24 ft during the week. Stopes producing some good ore. Shipped \$5,000 for the week.

ELKO CON.—The main west crosscut on the 200 level has attained a length of 85 ft, no change in the formation. The main east crosscut, same level, has been advanced 7 ft. Thus far the formation is favorable.

NAVAJO.—The east crosscut on 950 level has been advanced 10 ft during the past week. West crosscut, same level, advanced 8 ft. South drift 450 level advanced 13 ft. North drift 350 level advanced 21 ft. The stopes are yielding the usual amount and grade of ore.

ARIZONA.

GROOM CREEK.—*Prescott Miner*, Jan. 4: Billy Davis, of Groom Creek, informs us that 60 ft of his 75 ft contract has been sunk on the "110" mine. At 75 ft drifting will be commenced and hoisting works erected. At the present depth the vein is 5½ ft wide, and assays \$201 to the ton. Recent developments on the Chicago have disclosed very rich ore bodies, and during last month over \$10,000 worth of mineral, most of which shows native silver and fine gold, was taken from the mine.

PINE SPRING.—*Prescott Courier*, Jan. 4: The shaft in Gavin & Co.'s Pine Spring mine is down 125 ft. There are 2 tunnels, one 42 and the other 30 ft. Water, in small quantities, is coming in. There is a great deal of very rich ore in sight in shaft and tunnels. The hill in which this famous mine exists appears to be a common centre for siliceous units. The Co. will soon commence shipping ore.

CHRISTMAS GIFT.—*Globe Chronicle*, Jan. 5: The *Enterprise* says: We reported in the last issue that the Christmas Gift mine was likely to be sold this week. It is now an accomplished fact, Messrs. Eels & Chamberlain, of Cleveland, Ohio, being the purchasers at \$90,000 cash. The Christmas Gift vein is five ft wide, two ft of which gave an average of \$40 gold, and three ft an average of \$476 gold per ton. If there is a gold mine in the territory that can equal this we have not heard of it. It is said that there is one ft of the vein that will average \$1,000 per ton.

NOTES.—Mohave county *Miner*, Jan. 6: Arthur Macy, a graduate of Columbia School of Mines, New York, has been appointed Supt. of the Silver King mine, Pinal county. We are pleased to record the fact that a good streak of ore has been struck in the face of the 100 level of the Cupel mine. The ore streak is from four to eight inches in width and will assay in the neighborhood of \$400. There are five men working on the Lone Star mine. The Schuyllkill mine at Chloride is looking well. Three ft of solid galena in the face of the drift. Ore is being taken from this mine at the rate of a ton and a half a day 40 the man. The ore will average 25 or 30 ounces in silver and over 50 per cent lead.

THE QUIJOTOS.—*Logan Cor.* of *Prescott Miner* Jan. 4: The mines are 80 miles southwest of Tucson and about the same distance south of Maricopa and Casa Grande. Each of the three places are ambitious to become the shipping point for the camp, Tucson so far having the lead. Two town sites have so far been located—Logan and New Virginia—and numerous town lots have been sold in each. At present there is no work being done on the mines, and the deepest thus far reached in 300 ft on one location, with plenty of rich ore in sight to make further prospecting interesting. When work is resumed on the mines, which will be done as soon as the owners have completed surveying their claims and settled with adverse claimants—of whom there are already several—employment will be given to about 30 or 40 men, and there are now in the camp four or five times that number of practical miners; so those who contemplate coming here will do well to wait until a few months' developments make the employment of a larger force possible. Besides the Peerless, Pearl and other mines bought by Nevada parties, there is a wide field of comparatively unencroached on ground in the district to tempt prospectors; and already several new claims of fair promise have been located, the quartz generally containing free gold and going well in silver.

A TUNNEL THROUGH THE MOUNTAIN.—The *Florence Enterprise* says: F. A. Adams returned from the Quijotos this week. He says Charlie Beckwith has laid out a new town site on the west side of the mountain, and parties are coming in and taking up the lots at a lively rate. Sufficient water for camp purposes can be obtained on that side of the mountain, at a depth of 35 ft below the surface, and it is probable that the new town now starting will give Logan City a lively race in the matter of growth and business. Hank Smith, the Bonanza firm Supt., has arrived on the ground, and is preparing to drive a tunnel through the mountain, 800 ft below the highest point on the Peerless claims. It will not require a tunnel over 500 ft long to pass entirely through the mountain at the base, and as the work will be pushed with all possible speed, we shall soon know the probable future of this property. If the tunnel should open up an ore body \$10,000,000 would not buy the claims.

ANOTHER DISCOVERY.—The *Tucson Star* says: Miners just from the Quijotos report that another big strike has been made about 30 miles southeast of the great bonanza camp, and those who have seen the ore and talked with the men who made the discovery do not hesitate to say that it is the most extensive discovery that has ever been made in this country.

COUNTER CLAIMS.—The *Pinal Drill*, of 5th, says: The Quijotos fever is evidently abating. Hundreds have arrived at the foot of the mountains and found feed scarce, and water two bits a gallon. There have been several locations made upon the ledge on ground claimed by the Bonanza Kings. Some of these are said to cover the ground from which the rich ore was taken that has been shipped. The Co. hold the ground with men hired at \$200 per day. The exiled locators have retreated to Tucson. They ask prices high up for their various small parts of the ledge, \$100,000; \$150,000 and so on. It is likely to take a long time before this war is settled.

COLORADO.

IDAHO SPRINGS.—*Gazette*, Jan. 5: The Mott Sampling Works is a great boon to this camp. A

miner can obtain his cash for as small a quantity of ore as 25 pounds. A *Gazette* reporter was informed by manager Mott that the small lots which have been purchased by the works for 1883 aggregate thousands of dollars.

Twelve hundred tons of ore treated at the Mott Public Sampling Works netted the owners \$75,000, showing the average value of the ore produced in this vicinity to be \$62.50 per ton. Taking into consideration the charge for crushing and the excessive rates of the railroads, the price of smelting, etc., it shows this to be anything but a low grade camp.

BULLION CAMP.—At a depth of 35 ft in the shaft of the Little Ute lode, in Bullion camp, 16 inches of a pay streak has been exposed. A sample assay from the whole streak ran 315 ounces in silver. The quartz carries large quantities of gray copper. This property is now owned by Messrs. Elliott, Baron and Maroney.

IDAHO.

BANNER.—*Statesman*, Jan. 5: Mr. Albert N. Hull informs us that he received a letter a few days ago from James Monroe, who is now in New York, stating that the Elmira Co. had sold the Banner mine to a New York Co. for \$300,000, and the money was all paid down. The property sold embraces the mill and all the mines, some 15 in number, including the famous Banner mine, in the Banner district, 28 miles northeast of Idaho City, in Boise county. The Elmira Co. took out last summer \$109,000 in a 100 days run of the mill. Messrs. Hull & Monroe own an extension adjoining the Banner mine which prospects as well as the Banner and which he has an offer for and will probably sell before he returns from New York.

GAMBRINUS.—*World*, Jan. 1: Joe Voshay arrived here Friday evening from New York, where he went some time ago to endeavor to get a company to take hold of the Gambrinus mine, near this place, and was successful, we are informed. He also induced an eastern company to send out representatives to look at the Bruneau country with a view of digging a big irrigating canal. Joe left Saturday morning for Bruneau.

GREENHORN GULCH.—*Wood River Times*, Jan. 2: There is about two ft of snow on a level in the gulch. The road was broken to the Imperial group of mines yesterday. A teamster went up with 1,500 pounds of supplies. He would unhitch his horses, drive them ahead a piece, then come back for the sleigh. This would be repeated until he got to the mines. It is about ten miles to the mines, and a part of the way the snow was two and a half ft deep.

Contract work is being done on the Veta Grande group.

PARKER MINE.—A short time ago four men were put to work sinking an incline on the ledge, and on Christmas Eve, at a depth of about 100 ft, they cut into a body of solid ore which proved to be over five ft wide. The drift has since been continued, until the sides and face of it are all in solid ore. This ore is a solid mixture of chlorides, carbonate, azurite of copper, and galena, and assays as high as 2,870 ounces per ton. This is from selected samples, and is no reliable indication of the value of the ore per ton. An average sample, however, taken from a stratum which constitutes fully one-third of the width of the ore-body, went 666 ounces silver and 62½ per cent lead per ton. An average sample of the iron ore or gangue of the vein (which has heretofore been thrown off the dump as worthless) was found to carry 478 ounces per ton.

ATLANTA.—*Ketchum Keystone*, Jan. 2: Twenty-two men are at work in the Monarch mine, and the mine is looking well. Twelve men are working in the Buffalo, six are employees of the company, and six working in the shaft by contract. Machinery and timbers are on the ground for new hoisting works, which they will commence to erect about March 1st. At the same time a large force of men will be put in the mine. The Leonore mill was completed in the fall and made a 20 days run on Leonore ore. The mill worked like clock work, and gave entire satisfaction to the company. Owing to some dissatisfaction among members of the company it was closed down, but matters will permit of the resumption of work which will take place in about two weeks and continue through the winter. Owing to delays in the transportation of machinery the Tahoma mill is not completed, but will be as early in the spring as the weather will permit. The Atlanta mine, owned by Julian Hill and others, is being worked by a force of three men, who are extracting high grade ore, and the mine is looking better than ever before.

ERVINE MINE.—John H. Harris is running two tunnels to tap the Ervine mine, on Boyle Mountain, at the depth of 360 and 485 ft. He informs us that several large bodies of 220 ounce ore have been struck, and that the mine is looking better than ever before.

MONTANA.

ANOTHER EXCITEMENT.—Fort Benton Cor. *Butte Miner*, Jan. 5: Just now the absorbing topic here is the contemplated invasion of the Blackfoot Reservation by organized parties who know the value of the magnificent country occupied at present by the redskins. So intense is the excitement that scarcely any other subject is talked about. The papers are full of it, and the *River Press* announces its intention of publishing a "boom edition" devoted entirely to the Reservation subject. The richness of the Bear Paw country in placers and gold and silver ledges has been known for many years, but prospectors and miners have been kept out by the proscriptions which environ the National Indian reservation. In 1864 a party organized by a man named Keyes at Fort Benton had scarcely entered the reservation when they were attacked by the bloodthirsty Blackfeet, and the entire party massacred. This sequel proved a dampener on the ardor of adventurous prospectors, and of all the companies organized to enter the new gold fields not a single party made a start. The secret of Keyes' rich diggings died with him. In 1868 a small party went into the Bear Paw country and located some valuable placer diggings and quartz locations, but they were driven off. The locators of claims at that time are only waiting for the reservation to be thrown open to settlement to relocate their claims and commence active operations upon them. The matter of opening the reservation to settlement will come before the present session of Congress.

COUR D'ALENE.—*Butte Miner* Jan. 2: A man well known in Butte as an old miner and prospector was interviewed by the *Miner's* reporter on Friday. He said that with two other men he left Butte the latter part of October, as the representatives of a pool, composed of a dozen Summit Valley miners, who furnished them with expense money. They had undertaken to cross the range from Heron Siding. There being no trail, they lost their bearings and wandered about the mountains for several days. When at a point about 30 miles northeast from Eagle City they found promising gold croppings. They went into camp for ten days, during which they prospected the ledge, by several open cuts and a shaft ten feet deep, developing a vein from two to four feet wide which was traced by the croppings a distance of about three miles. He had assays of the quartz showing from \$25 to \$482 to the ton, and showed a beautiful specimen of white quartz which was ribbed and streaked with free gold, and would assay way up into the thousands. After staking off claims for their party and posting notices on the ledge, they descended into a narrow gulch, through which ran a good sized creek. Following down the stream they came to a valley stretching out northeast and southwest a distance of 14 or 15 miles, and from a quarter to a half-mile wide. They went into camp that night at the head of the valley, and were overtaken by a snowstorm. During the day they were snow bound, and one of the party amused himself by panning out a few shovelfuls of dirt from the creek, by which they had built their fire, and was astonished to get about 20 cents to the pan in coarse dust. They remained in the valley about a week, and prospected in eighteen or twenty places, from which they scraped the snow. They found gold wherever they prospected, and our prospector yesterday exhibited four and a half ounces of coarse gold, and bits of float quartz carrying free gold, as a result of their labor in the valley.

OREGON.

NOTES.—*Jacksonville Times*, Jan. 4: The Sterling Co. has not commenced piping as yet, but does not need much more water to set both pipes in motion, as the ditch is half full now. Several of the miners are making good use of their reservoirs. The ground is well soaked and not a great deal more rain is needed to set all claims in motion. Sargent Bros., of Steamboat, have enough water to groundsluice with. Cadwell & Sons have started up their giant, J. D. Shener & Co. are expecting to receive a quantity of hydraulic pipe soon. Jack Layton is making the gravel fly at his extension mines on Farris' gulch. A. Stevens and J. M. Kendrick are about commencing to mine on Jackson creek.

NEW MEXICO.

GOLDEN RULE.—*Silver City Enterprise*, Jan. 4: The Golden Rule mine and mill started up last week with nearly as large a force of men as were employed when work shut down. The men were paid off in full, and those that chose were allowed to continue, while others, who during the temporary embarrassment of the company made themselves obnoxious, were requested to seek other employment. The return from the last shipment of bullion, previous to the closing, was sufficient to pay off all indebtedness of the mine and mill and leave a surplus in the hands of the manager. From E. Fender, who on Tuesday returned from the Golden Rule, we learn that the mine is improving with every ft of work done, and at the depth of 208 ft a five ft vein of the usual grade ore is being worked upon. He states that the mine will much more than pay expenses besides the cost of development.

STEEPLE ROCK.—*Cor.* of *Silver City Enterprise*: Everything at the Carlisle is just beginning to boom. A town site has been located and the sale of lots commenced. On the first of the year all Chinamen must go, their places to be filled by white men. A much larger force than ever will also be worked, there being now an abundance of ore and water. Work is going on at the Nugget with the usual success. It is thought the owners will soon commence shipping ore, as they will, with their present force of men and with what ore they are ahead, be able to continue shipments, if once commenced. The mine known as the Diamond, which is the west extension of the Nugget, owned by J. Currie, of Steeple Rock, and Ross & Smith of Lordsburg, and on which 275 ft of work has been done with flattering results, will be worked to a still greater extent soon. Work on the Eagle has been suspended for an indefinite period.

THE GOLD FIND AT SAN CARLOS CAMP.—*Las Vegas Gazette*, Jan. 2: There were scores of prospectors out in the hills yesterday, in the neighborhood of the old San Carlos camp. As yet no more nuggets have been found like that picked up at the Hallie claim, although considerable dirt has been washed which produced quantities of the yellow stuff. Any number of good looking rocks, carrying gold that could be seen with the naked eye, were brought in. Most of the specimens showed silver indications, such as argentiferous galena, together with strong traces of copper. A new excitement was raised yesterday by an extraordinary discovery on Tilden street, east side. While digging a well at Chris Weigand's pop factory the glittering stuff was found and fifty colors came from a single pan. A well on Charlie Wright's property, near by, showed a like result, and a stake bearing a location notice signed by C. L. French, is planted on the site. The finds were kept quiet, but got out, and everybody became interested at once.

NOTES.—*Las Cruces Republican*, Jan. 5: Assessment work is being done by William King on the Davis group, in the Organs. King has just finished work on four claims in the Jarillas, belonging to the same men (Oliver Davis & Co.). The Dixie has shown up splendidly. Perkins and Bickford have finished their contract on a claim in the Jarillas belonging to Hoopes, Hampton and Dr. Rogers. It showed over three ft of good copper ore. The assessment worked on the Hawkeye has shown up a good body of ore, some of it very rich, and similar to that of the Little Buck. The pumping of the water out of the Memphis has lowered the water 18 inches in the Rio Grande mine, nearly a mile away, showing there is a subterranean connection between the two. Both mines are situated at an elevation of 1,700 ft above the plateau of the Rio Grande.

The Growth of Small Industries in the Foothills, Mines and Mountains.

What is to be done with the on-coming generation in California is a question that is exciting much interest and eliciting some discussion among those who assume to deal with these ethical and economic subjects, and the thoughtful generally. Here, as everywhere else, the question resolves itself into one of employment, mainly what is there for the youth to do that they can do or can be induced to. The young people of California are not worse, perhaps, than those of most other countries. The average youth are inherently about the same the world over. Nevertheless, the question with us becomes a little more difficult of solution, by reason of certain industrial conditions and social peculiarities that here obtain.

In the first place, our juvenile population, already large, is increasing rapidly, California being a prolific country. Though not particularly vigorous, they are apt to be tenacious of life, a large percentage of those born surviving the perils of adolescence and reaching the adult state. They are a little precocious, growing fast and maturing early. As a general thing they have come to stay, being like the rest of us, attached to California and not likely to seek residence elsewhere. They would not be apt to thrive if they did so. Like some other products of California, the native horn do not well bear transplanting. The *Sequoia* it is said will not grow elsewhere. Other countries, if they become overpopulated or accumulate too many of an undesirable class, find relief through emigration. But through no such means can we ever find relief from any obnoxious or too numerous class, should there be need for it. But this aspect of the case is not serious; there is here room for all and means enough for insuring all a comfortable subsistence, were such means turned to good account.

In older communities it is the youth of the larger cities who most stand in need of work. With us it is the youth of the rural districts, or at least certain portions of them, who so want work supplied to them. In most other countries there exists in the cities a large surplus of the young, for whom it is difficult to find suitable employment, though outside of these large towns there is apt to be enough for all. Here these conditions are measurably reversed, the larger cities being the principal centers of our mechanical and manufacturing industries, thereby affording much suitable employment for the young. The great agricultural valleys of California are also capable of supplying work for all classes, old and young.

But there remain the mountainous districts of the State, with their valleys and out-lying foothills containing resources of a varied kind, but no one of which is capable of sustaining a large population. Possessing a tolerably good soil, and being for the most part well wooded and watered, these districts are admirably adapted for fruit raising and the culture of the vine, there being also much land on which, with careful tillage, fair crops of the cereals can be produced. This is the region of the gold mines and other mineral deposits of value. Taken as a whole this is not a bad country for stock, there being much good summer pasturage—also mast for swine. While the mining districts were never much more populous than they are to-day, the majority of the inhabitants formerly consisted of grown men, mostly engaged in mining; whereas, much the larger number is now composed of women, children and adult youth, while of the men, not more than three-fourths follow the business of mining, a great many having turned their attention to cultivating the land, raising stock, making lumber, and to various other pursuits.

Having originally gone to the mountains for the purpose of mining, the most of these men stuck to that business as long as it would pay; nor did they in all cases wholly abandon it after devoting a portion of their time to other pursuits; so that we have now the spectacle of farming, mining and stock raising, being in many instances carried on here by the same individual, and this quite successfully, there being seasons of the year when he can give his entire attention to some one of these branches without detriment to either of the others. Thus, in the northwestern counties, where objections have been made to hydraulic mining, this branch of business can be engaged in along through the winter and early spring, when it can be prosecuted to the best advantage, and during which the farmer-miner has not much else to do. Later in the year, when the grain harvest being over, there comes another season of leisure, then, and not before, the river beds can be worked to advantage. As operations in the quartz and drift mines can be carried on equally well at all times, parties in working these can consult their own convenience. Between the closing of river-bed mining and the advent of winter comes another interval of rest, which is to be availed of for gathering in the beef cattle, now in good condition, and driving them over the mountains or off into the lower country to market; and so the inhabitants of these foothills and mountain regions are coming to find their time fully and profitably employed, the combining of so many minor industries enabling them to make a good livelihood in sections of the State where only a few years ago their ability to do so was far from being assured. In a short time there will be added to

the occupations now pursued others for which these sections of the State are well suited, such as fruit drying, curing raisins, making wine, sericulture, etc.

Throughout nearly all parts of the mining regions the condition of the inhabitants shows improvement through the multiplicity and growth of these small industries, the change in some of the more northerly-lying counties being especially noticeable. From Trinity, for example, which not long since was importing its beef, one stock-raiser has already, this season, driven over the mountains into the upper Sacramento valley five hundred head of fat cattle, which were there disposed of for a good price. Limiting observation to one branch of business or a single neighborhood the changes effected seem small, but extended over the whole field they are seen to aggregate a great deal.

It is to be set down to the credit of the young people of the interior that they do not evince such a desire to leave their homes and seek employment in the cities as is common with this class elsewhere. This argues well for their future. Notwithstanding the gloomy forebodings of the past the present industrial outlook presents many features of encouragement, this here noticed being one of the most hopeful.

Watching the unfolding of coming events we shall hope for the evolution of such industrial system as will meet our many-sided wants, and thus work further surcease of our fears for the future of this, our California.

How the Debris Decision is Received.

Dispatches from various localities in this State show how the news of the debris decision is received, as follows:

DOWNIEVILLE, Jan. 8.—A feeling of general indignation prevails all classes in regard to the debris decision as unjust and oppressive, and a deadly blow at the mining industry of the country.

GOLD RUN, Jan. 8.—Miners and citizens feel that Judge Sawyer's decision is unjust, and everybody is indignant. All property is ruined and all feel that the general government should settle the trouble.

CAMPTONVILLE, Jan. 8.—Judge Sawyer's decision had to some extent been anticipated by the miners, yet it has a very depressing effect on all kinds of business here.

NORTH SAN JUAN, Jan. 8.—The decision of Judge Sawyer in the debris case was received here on yesterday afternoon. It created but little, if any, despondency among the miners and business men, as they think matters will eventually come out all right, and that the interests of the miners and farmers alike will, in the near future, be protected.

AUBURN, Jan. 8.—As a matter of course the decision of Judges Sawyer and Deady is not very acceptable to residents of Placer—Gold Run, Dutch Flat and vicinity being more seriously affected than any other portions of the county. On the Forest Hill Divide but a small amount of hydraulic mining is done compared with the other kinds of mining. No general demonstration was made here. Evidently we must grin and bear it, although it will add to the financial depression hereabouts.

RED BLUFF, Jan. 8.—The decision of a perpetual injunction in the debris case does not create as much comment or feeling here as in counties south of us, as we are exempt from hydraulic troubles. But those who are aware of the decision express a degree of satisfaction which proves that our community is in favor of the farmers winning. Many believe it will help the county by resurrecting the steamboat traffic, which is now prevented on account of the obstructions in the river.

JACKSON, Jan. 8.—The perpetual injunction in the debris case does not materially affect the mining interests of this county, as there are no hydraulic mines of sufficient magnitude to cause injury by their tailings.

CHICO, Jan. 8.—The decision of Judge Sawyer is received with satisfaction by the people in this section. The farmers here, although not sufferers from mining debris themselves, have a strong sympathy with those who are—especially our near neighbors in Marysville.

COLUMBIA, Jan. 8.—The general expressed opinion of representative men of this place relative to the decision in the debris case is that it is unjust.

SONORA, Jan. 8.—The feeling prevails here that the decision in the debris case will work an injustice to the miners and mining interests of the State. The miners having purchased their claims in good faith, the general government should provide some means by which they can work their claims, they having equal rights with the farmers.

STOCKTON, Jan. 8.—Public sentiment in this section is almost unanimous in approval of Judge Sawyer's decision in the celebrated debris case. The decision was not generally known yesterday, and not until to-day was the matter discussed to any great extent. Some think that the decision hardly goes far enough, and that an opening is left for mischief to be perpetrated by exempting from injunction those miners who can confine and take care of their debris. The decision has caused no excitement whatever in this community, but has been received with quiet yet cordial approval.

COLUSA, Jan. 8.—The decision of Judge Sawyer in the debris case was received here with the greatest satisfaction. One hundred guns are being fired.

YONE, Jan. 8.—The first news of the decision of Judge Sawyer in the debris question was received here this afternoon. While this community is not directly affected by the decision, yet it will be eventually. The farmers approve of it emphatically, while the miners and those who sympathize with them are equally emphatic in their disapproval.

The Geddes Company are pushing prospect work in the Geddes and Bertrand mines with Burleigh drills. It is more than probable, if new ore bodies are discovered, that they will prove more profitable to the company than those already developed, as the rich ore from the latter had already been goned out by tributaries before the present company came into possession of the mines.

Academy of Sciences.

The annual election of officers of the California Academy of Sciences was held on Monday, with the following result: President, George Davidson; First Vice-President, H. W. Harkness; Second Vice-President, H. Hermann Behr; Corresponding Secretary, Samuel B. Christy; Recording Secretary, Charles G. Yale (of the MINING AND SCIENTIFIC PRESS); Treasurer, Etisha Brooks; Librarian, Carlos Troyer; Director of Museum, W. G. W. Harford; Trustees—Charles F. Crocker, Robert W. Simpson, George E. Gray, Thomas P. Madden, Ralph C. Harrison, Jas. M. McDonald, Lewis Gerstle.

The report of George E. Gray, President of the Board of Trustees, was read, showing that the money donated to the association by Charles Crocker was being used for the purposes for which it was given. Several thousand persons visited the Stanford-Crocker collection during the year at the Mercantile Library Hall. The expense of maintaining the collection was \$2,066.15. From rents, \$3,908 had been received and \$1,936.50 from members' dues. There was a balance on hand of \$1,631.72 and \$909 outstanding on the books.

The report of Charles G. Yale, the Secretary, showed that thirty-one members had been elected during the year, and that nine had been dropped from the roll. There were now 184 actual members and 132 life members belonging to the association.

The report of the Treasurer showed that \$9,885.24 had been received during the year from various sources and \$8,253.52 expended.

The report of the Director of the Museum briefly related the work performed during the year in the various departments.

The annual report of the Librarian showed that 100 books had been received from the various departments at Washington, 616 from various societies; and there were also 690 donations from individuals.

The Council of the Academy have the privilege of nominating, at the annual election, for honorary life membership, two members who have rendered valuable services to the academy. Four years ago Professor Davidson was elected, and on the following year Dr. H. Behr was chosen. The past two years the Council saw fit to make no nominations. This year, however, they took advantage of their power and nominated Dr. H. W. Harkness, who has distinguished himself by close scientific work in microscopic botany, and Charles G. Yale, who has served continuously as Secretary, gratuitously, for twelve years. Both gentlemen were unanimously elected.

On motion, a vote of thanks was tendered to Mrs. Dr. Curran for her botanical labors in behalf of the association during the past year.

The President read his annual address, and also a paper "On Astronomical Research." From these we shall quote on another occasion.

The Silver King Mine.

The annual meeting of the Silver King Mining Co., of Arizona, was held in this city last week. Colonel James M. Barney, B. A. Barney, J. L. Jones, Dr. W. H. Stanley and Aaron Mason were re-elected Directors. The officers were reappointed as follows: B. A. Barney, President; J. L. Jones, Vice-President; James M. Barney, Treasurer and General Manager; Joseph Nash, Secretary, and Arthur Macy, Superintendent. From the report of the latter it seems that the surface improvements at the mine have been the completion of the ore-house and the setting up of an engine and Blake Rock-breaker therein, the placement of one Sturtevant and one Boston air-blower, with piping. An addition on the east side of the engine-house for an engine, which furnishes power for the saw-mills, drives blasts and ventilating centrifugal blowers, furnishing air blast for the forges and occasional extra ventilation for the mine, as well as supplies power for drilling, nut and bolt cutting machines. An office building, 26x26 feet, two stories high, was completed the latter part of the summer. A much needed new change-house, 20x40 feet, was erected last month. A permanent fire apparatus has been completed, and all the buildings are now protected by seven fire plugs and attached hose and nozzels, placed at the most available points and ready for instant use.

The work in the mine has been confined to the enlarging of the sill floor of the 510 level, the extension of the sill and extraction of ore from the stopes of the 714 level, as well as enlarging the winze between the 612 and 714 levels from 4x4 to 14x14 feet. The shaft has been sunk 102 feet, and a station completed for the 816 level. Nothing has been done on the 612 level, or any of the levels above the 510, so they remain about the same as they were a year ago.

There has been no appreciable change in the amount of water in the mine.

On the 510 level, the sill floor has been extended at intervals, until now its greatest length is 91 feet, and greatest width 72 feet. A stope was started, but only enough ground taken out for one set of timbers. The total space excavated in this level is 37,100 cubic feet, of which 16,996 cubic feet have been taken out this year. It is almost entirely in ore and the sill is now being extended with gratifying results.

The 714 level has been extensively exploited

during the year. The sill floor has been largely extended, offering increased stopping ground. During the year the volume of ground extracted has amounted to 410,418 cubic feet, and the total space excavated amounts to 657,769 cubic feet.

The method of timbering and the dimensions have not been changed. The system of pillars built with waste rock has been extended continuously. The character of the ore has not altered materially. The ventilation has been good excepting during the extreme hot weather, when additional air was carried to the 714 level from a centrifugal blower on the surface.

The consumption of cord wood at the mine has been 941½ cords, costing \$9,679.62, or an average of 2.53 cords at a cost of \$26.51 per day. The present consumption is about 2½ cords per day.

The amount of ore hauled to the mill was 23,172 235-2000 tons.

At the mill to handle the pulp from 20-stamps there are now 12 Frue Vanners, four new ones having been put in during the year. These Vanners are now run by a new special vertical engine.

A six-inch well was sunk to a depth of 150 feet in the early part of the summer on the east side of the mill, for the purpose of increasing the water supply; a Thompson and Evans deep well pump was put into it and now furnishes 1,000 gallons per hour. An artesian well-boring machine has recently been purchased with a view of sinking two additional wells at the mill.

The amount of cord wood consumed during the year at the mill was 3,108 cords, costing \$26,783.06, or an average of 8.51 cords, costing \$73.87 per day.

The general appearance of the mine is very flattering, recent developments having exceeded my best anticipations. The close of the year finds us with a very large reserve of ore at the mill. The ore house and the chutes in the mine are full, and a large quantity broken and ready for sorting.

In the execution of the year's work, material aid and assistance have been given by Messrs. F. H. Blake (metallurgist in charge at mill), Robert Bowen (mine foreman), J. W. Kenney (chief engineer), and G. L. Voice, Kenneth McKenzie and W. H. Benson. Very respectfully submitted,

ARTHUR MACY, Supt.

Secretary's Report.

The receipts and disbursements from January 1st to December 31, 1883, were as follows:

RECEIPTS.	
Balance on hand.....	\$30,385 67
Sales of Concentrations.....	592,503 53
Total.....	\$621,889 30
DISBURSEMENTS.	
Sampling and assaying.....	8 59 10
Expense.....	22,349 10
Insurance.....	750 00
Law.....	1,012 00
Purchase adjacent mines.....	14,000 00
Freight.....	19,620 81
Merchandise and lumber.....	49,670 18
Superintendent's drafts.....	332,501 46
Dividends.....	175,000 00
Balance on hand.....	25,156 05
Total.....	\$621,889 30

Iridium.

The chief source of iridium is the mineral iridosmine, which occurs in very hard, shining, metallic grains in many placer deposits, associated with gold. The ore consists mainly of the rare metals iridium and osmium, together with smaller quantities of rhodium and ruthenium. Platinum and palladium also are sometimes present. The chief commercial sources of iridosmine are in the Ural mountains; but it occurs also in Brazil, and a considerable amount is brought from California and Oregon. Being as heavy as gold, it accumulates with the latter in the placer washings, and is easily recovered and saved. The harder grains are used in tipping gold pens, and the other portions are converted into iridium oxide. The latter substance serves for a permanent black pigment in decorating fine porcelain.

When iridosmine, which is practically infusible, is heated to whiteness in contact with phosphorus fusion takes place. The fused product, heated with lime, loses phosphorus, and a subphosphide of iridium is left. At the same time osmium is eliminated by volatilization as oxide. This so-called fused iridium is now manufactured under Holland's patent by the American Iridium Company, of Cincinnati. It is steel-white in color, harder than steel or even agate, is practically infusible in any furnace, is insoluble in the strongest acids, and incapable of rusting. These properties are likely to create a demand for iridium, which is now being introduced into commerce for a variety of purposes. It is not only used for gold pens and for the points of stylographs, but also for the knife edges of fine balances, for the tips of rubber-burning tools, for wire draw-plates, etc. Recently Prof. W. L. Dudley, of Cincinnati, has succeeded in electroplating with iridium, and has obtained excellent results.

To a considerable extent iridium is alloyed with the platinum used for chemical purposes, inasmuch as it gives the latter metal increased rigidity and hardness. The standard meters of the International Commission on Weights and Measures consist of ninety parts of platinum to ten of iridium.

Crude iridosmine is now worth from \$2 to \$5 per troy ounce, according to purity. "Fused iridium" sells at about \$10, pure iridium (refined only abroad) at about \$20.

THE ENGINEER.

The Corinth Canal.

Some further details have been received respecting the ship canal now being cut, in the most literal sense of the word, through the Isthmus of Corinth. The actual length of the canal, when finished, will be just under four miles. The entrances to the canal will be 328 feet wide, diminishing to 72 feet, the depth being 26 feet. The nature of the ground through which this canal has to be cut is composed of three distinct kinds: firstly, from the Gulf of Corinth, through a plain consisting of sand and alluvial soil, for a distance of just over three-quarters of a mile; secondly, through a mountain range, varying in height from 130 to 260 feet, of the length of 2½ miles; thirdly, beyond the mountain range to the sea, in the Bay of Calamaki, the proposed canal will traverse a little plain of the length of about two-thirds of a mile, composed of alluvial soil and rocks. The contract price of the work is about \$5,000,000.

ANOTHER triumph of American engineering over natural difficulties is the cantilever bridge across the Niagara river. This is one of the most remarkable works of modern times, and has the longest double track span in the world—900 feet over the river—and will be opened to travel early in December. The idea of spanning the deep gorge of the Niagara with a bridge built out with arms approaching each other from opposite shores was a bold one. But the work has been prosecuted without serious mishap or delay, and the first railroad bridge on this principle is now so nearly finished that it is pronounced a completely successful undertaking. The building of the bridge has been regarded with great interest by engineers and railway managers in various parts of the world. Every American will take an honest pride in this grand achievement of his countrymen.

MAMMOTH PNEUMATIC TUBE.—One of the most extensive schemes yet devised, and one which, if it should prove successful, will be one of the most beneficial, is the proposition to construct a pneumatic tube between New York and Chicago for the purpose of transmitting letters, grain samples, jewelry and other small, light packages. Way stations will be established at Cleveland, Buffalo and other points. The pipes will be of iron, four inches in circumference, and the cost of laying them is estimated at \$4,000 per mile. The price for carriage will be five cents for letters and ten cents for parcels, and the boxes holding the goods will make the trip between the two points, it is believed, in four hours.

RAILROADS IN 1883.—The advance sheets of *Poor's Railway Manual* for 1883 show a mileage at the close of 1882 of 113,329 miles, 11,591 having been constructed within the year. The average mileage operated for the year was 107,158. The amount of share capital issued by the several companies up to the close of their respective fiscal years was \$3,456,078,196, an increase from the previous year of \$385,254,585. The funded debts of the several companies amounted to \$3,184,415,201, an increase from the previous year of \$352,554,496.

AN IMMENSE DAM.—A French engineer in Brazil has lately been selected to construct what will probably be, when completed, the largest dam in the world. The main dam will be 940 feet long by 58 feet high, and two smaller ones will close side depressions. This work will, it is calculated, back the water over 1,500 acres, and retain 14,000,000 cubic meters of water, sufficient to provide for all the cattle of the regions during three years, and for the irrigation of 5,000 acres of flat bottom land alongside the river bed below. The rivers of Ceara flow in the wet season alone.

A SECOND FOUR TRACK RAILROAD.—The Pennsylvania Railroad Company is steadily extending the third and fourth tracks on its main line, in order to facilitate the movement of the enormous traffic it is now handling, and which is constantly growing. The company is not only using all its available cars but has been compelled to lease from other companies several hundred freight cars while additional rolling stock is being built. The Pennsylvania is now the largest coal and coke carrier in the United States.

THE ELECTRIC LIGHT.—More than a dozen steamers plying between New York and Liverpool are fitted up with electric lighting machinery. Probably three times as many are so fitted out on the various other lines of ocean-going steamships. The British steamers are largely supplied with the Siemens and Swan apparatus but the other systems are well represented.

EXTENSIVE PROJECTS.—In addition to the scheme for bridging over the Straits of Messina, other projects in connection with the same matter are before the attention of the Italian government. A large ferry to contain twenty-four railway carriages has been proposed to the Ministry of Public Works, by Signor Colabretto. A tunnel is also spoken of, the construction of which is estimated to cost \$15,000,000.

USEFUL INFORMATION.

Imitations of Costly Leather.

The custom of carrying lunch reticules, money purses, and traveling bags of leather has made an increased demand for the leather from rare animals, or for leather of attractive appearance. As the natural supply of alligator and the great python or boa skins is not sufficient to keep up with the demand, these skins—or the leathers from them—are imitated very largely by using the leather of commoner and cheaper skins. Even seal leather, goat leather, and kid leather, or morocco, are imitated. The surface of alligator leather consists of almost exact rectangles or squares, separated by deep furrows, the squares gradually diminishing in size as they recede from the center of the skin. The boa leather is in diamond shaped patches, forming a fine network, and is very elegant, the division lines being very fine. Seal skin leather is a fine diapered or arabesque pattern of irregular divisions raised and depressed. Goat leather is crossed in regular lines at acute angles, forming minute elongated diamonds.

As some of these leathers are too costly to be furnished at low prices, the million who desire the best, but cannot always afford the cost, are supplied by fair imitations which are not as durable as the genuine, serving in part the purposes of the costly leathers. These imitations are made by the aid of photography. A genuine seal, alligator, boa, or other costly skin is photographed, then printed on sensitive gelatine, the parts not acted upon by light dissolved out in water, and a cast or an electrolyte plate then made in copper or type metal, as practised in the reproduction of engravings, and then the metal plate and the smooth leather of some domestic animal are passed between rollers under pressure, and the figure on the plate is permanently fixed on the leather by great pressure. Any of these leathers may be stained, colored, or dyed to any tint desired; but plain black or the color left by the tannin is generally preferred. —*Scientific American*.

China Still Ahead.

It is claimed for many important inventions of both America and Europe that they are merely re-inventions that have been known in China for centuries. Now comes Dr. Macgowan, a resident of China for thirty years or more, who says in a communication to the *North China Herald*, that illuminating paint has long been known, made and used in that country. The Chinese use powdered muscle shells instead of oyster shells in the manufacture of the paint. He says the invention is quite ancient; that the emperor, Tai Tsung, who flourished towards the end of the tenth century of the Christian era, received a picture which was luminous by night. The picture represented, by night, a cow lying within a fence, while by day the cow appeared as browsing outside of the inclosure. His majesty asked for an explanation from his ministers, but they were no better informed than he. At length some one informed the emperor that the effect was produced by mixing Southern Sea pearl-paste with a pigment which at night became luminous; and that the day picture was made of a powdered reef-stone. In after ages the picture was attributed to the genii, whilst some denied its existence altogether. Dr. Macgowan shows, by extracts from a Chinese writer of three centuries ago, that the tradition of the art had not died out.

EAST INDIAN WOODS.—The *London Timber Trades Journal* has the following regarding East India furniture woods: Teak wood is light, soft and red, and has no heartwood. It is not eaten by white ants, and is highly valued and universally used for furniture of all kinds, and for door panels and carving. In Bengal and Assam it is the chief wood for making tea boxes, but is getting scarce on account of the heavy demand. Chickeraasi or Chikrassi wood is a large tree with bark reddish-brown and deeply cracked. The heartwood is hard, varying from yellowish to reddish-brown, with a beautiful satin lustre. It seasons and works well, and is used for furniture and carving. Nagasar wood has dark-red heartwood, extremely hard. It is used for building, for bridges, gun-stocks and tool-handles; but its more general use is prevented by its great hardness, weight, and the difficulty of working it. Pitraj wood is reddish, hard, close, and even-grained, but is little used. In Chittagong, canoes are sometime made of it. Kandeb wood is light red, shining, cross-grained and moderately hard. It is used largely in Chittagong for masts, spars and rafters, and sometimes for small boat building.

THE STRUCTURE OF HAIR.—A single hair now enables the anthropologist to judge in what division of the human species he will class its owner: there is no mistaking a Chinese for a European, or either for an African. The cross section of this single hair, examined microscopically by Pruner's method, shows it circular, or oval, or reniform. Its follicle curvature may be estimated by the average diameter of the curls, as proposed by Moseley; its coloring matter may be estimated by Sorby's method. There has been even a systematic classification of man published by Dr. W. Miller, of the Novara expedition, which is primarily arranged according

to hair, in straight haired races, curly haired races, etc., with a secondary division according to language. Though we cannot regard such a system as good, the wonder is that it should answer so well as it does; indeed, nothing could prove more clearly how real race distinctions are than a single bodily character should form a basis for rationally mapping out the divisions of mankind.—*E. B. Taylor, in Natur*.

MAHOGANY.—The manufacture of mahogany furniture has, perhaps, increased four-fold within the last two years. This increase comes from the demand for high-priced furniture, as well as from the deterioration and scarcity of black walnut. This beautiful wood is now largely being made use of for interior finish—many of the finer houses, banks, insurance offices, etc., being finished with it. Its use is entering rapidly into the construction of railway carriages—a source of demand uniformly good for hard woods. The chief sources of mahogany are Mexico and the West Indies, and the United States takes 25 to 30 per cent of the whole exports.

BULGING OF RIFLE BARRELS.—A board of officers have tested a lot of rifles at the Springfield Armory to determine the cause of the bulging of the barrel, which occasionally occurs in practice. They find it due to the fact that the muzzle has been stopped by sand, caused by resting the muzzle in wet sand, or in dry sand after the gun has become foul from firing. This arrests the passage of the ball, so that the pressure is increased at the point of swelling. It is curious that sand produced this result where wooden plugs, driven in tightly and swelled by steam, failed to do so.

MUTUAL ANTAGONISM IN WOOD.—It is interesting, and may be instructive to some, to learn that certain kinds of woods, although of great durability in themselves, act upon each other in such a way as to produce mutual destruction. Experiments with cypress and walnut, and cypress and cedar prove that they will rot each other while joined together, but on separation the rot will cease and the timbers remain perfectly sound for a long time.

SHRINKAGE in lumber varies according to the tree from which it is made. Oaks will shrink in drying one-half inch to the foot; while the redwoods of California show no perceptible change, and the heavy Eastern or South American woods lose but little.

GOOD HEALTH.

Salicylic Acid as a Preservative.

The very extensive use of salicylic acid as a preservative of foods, wine, beer, cider, etc., and its use internally in the form of salicylate of soda as a medicine, especially for rheumatism, has been the subject of no inconsiderable discussion in medical journals, and among the medical profession in general.

The French Society of Hygiene recently made it a matter of extended discussion, in the course of which it was claimed by M. Durand that the addition of salicylic acid to beverages should be considered a punishable fraud, unless a label clearly indicating its presence was placed on the vessel. While salicylic acid is a very desirable agent for the prevention of fermentation in certain industries and as a medicine in some diseases, its use should be restricted to these two objects.

It was urged that this acid has a very unfortunate influence upon the human system, giving rise to affections of the ear and even sometimes producing complete deafness.

The society after consideration appointed a committee to investigate the subject, who reported as follows: "After having carefully considered this subject and studying the analysis of several substances containing salicylic acid, the committee would report that they find this substance dangerous, not only from the pernicious effect which it produces on the system, but also because its use permits the fraudulent introduction into foods of other objectionable materials, more or less unhealthy, especially in the wines of dried grapes and in beer. The committee concluded that any alimentary substance, solid or liquid, containing the slightest quantity whatsoever of salicylic acid or of its derivations should be considered dangerous, and that its sale ought to be prevented by law."

The French Minister of Agriculture and Commerce incorporated the above report in an edict which he has just issued, asking the prefects of the different departments to adopt proper measures for the suppression of the sale of articles containing salicylic acid.

On the other hand a very prominent German journal pertinently comments on the French edict by observing that the latest researches of Prof. Kolbe ("which appear to be entirely unknown to the French") very clearly prove that salicylic acid in the quantities used for the preservation of food is entirely safe, and that no second thought need be given to its employment.

The Prof. Kolbe above alluded to, has discovered a new and synthetical method of preparing this substance from coal tar, instead of from willow, as its name indicates. Whether this circumstance has an influence in prejudicing his mind in its favor is a matter which perhaps, should be health taken into consid-

eration. But our readers have now both the French and German side of the question, and must determine the matter for themselves, or await further investigation.

Reflex Nervous Influence.

It has oftentimes been cast up to physicians, by those who ought to know better, that the mysterious and ill-defined influence of "reflex action," is utilized as a shield to cover ignorance, and as a loophole to crawl through and escape when confronted with a morbid condition, the intimate nature and etiology of which they are unable to fathom.

That some men have availed themselves of this convenient and comprehensive term is undoubtedly true; but that such a thing as reflex action is a reality, and that it is a much more potent etiological factor of disease than is ordinarily believed, is also true.

By reflex action we mean that an impression made upon some nerve termination in one portion of the body is carried along this nerve to a center, and from there reflected, as it were, along some other nerve to a part of the body remote from the point of first impression, at which latter point its power to disorder healthy action is made manifest, while no morbid phenomena are observable at the point from which the irritation has really arisen.

This is a plain definition of "reflex action," devoid of all technical and superfluous words; and that diseased conditions frequently have such origin, no one of experience will deny.

But the general practitioner, we fear, does not take this factor sufficiently into consideration in the formation of his opinion of the cause of disease, and since, therefore, his remedies are directed rather to the effect than to the cause of the effect, he is met oftentimes with failure, when, did he but realize the actual influence of reflex action, and look to the proper point for his cause, and guide his therapeutics accordingly, he would have much better results.—*Med. and Surg. Reporter*.

THE PHENOMENA OF DEATH.—A Philadelphia physician has made a special study of the phenomena of death, both through his personal observations and those of others, and his conclusion is that dissolution is painless. "I mean," he explains, "that it approaches as unconsciously as sleep. The soul leaves the world as painlessly as it enters it. Whatever be the cause of death, whether by lingering malady or sudden violence, dissolution comes either through syncope or asphyxia. In the latter case, when resulting from disease, the struggle is long protracted, and accompanied by all the visible marks of agony which the imagination associates with the closing scene of life. Death does not strike all the organs of the body at the same time, and the lungs are the last to give up the performance of their functions. As death approaches, the latter gradually become more and more oppressed; hence the rattle. Nor is the contact sufficiently perfect to change the black venous into the red arterial blood. An unprepared fluid consequently issues from the lungs into the heart, and is thence transmitted to every other organ in the body. The brain receives it, and its energies appear to be lulled thereby into sleep—generally tranquil sleep—filled with dreams which impel the dying to murmur out the names of friends, and the occupations and recollections of life."

A NEW TREATMENT FOR NEURALGIA.—The latest agent introduced for the relief of neuralgia is a one per cent solution of hyperosmic acid, administered by subcutaneous injection. It has been employed in Billroth's clinic in a few cases. One of the patients had been a martyr to sciatica for years, and had tried innumerable remedies, including the application of electricity no fewer than 200 times, while for a whole year he had adopted vegetarianism. Billroth injected the above remedy between the tuber ischii and trochanter, and within a day or two the pain was greatly relieved, and eventually quite disappeared. It would be rash to conclude too much from these results in the face of the intractability of neuralgia to medication, but if it really proves to be as efficacious as considered, hyperosmic acid will be a therapeutic agent of no mean value.—*Lancet*.

DEFENSE OF VIVISECTION.—P. Bert, late Minister of Public Education in France, publishes an article in defense of vivisection. He says that savants do not resort to painful experiments upon the bodies of living animals except with heavy hearts. They do it unwillingly, and are often forced to control their own sufferings while so engaged. They are also bitterly opposed to all perversion and abuse of such experimentation by heartless or incompetent persons. Science, however, he says, cannot dispense with vivisection. It is for the benefit of humanity, and essential to the progress and development of human knowledge, and all efforts to prevent its perversion or abuse by legal restraints and regulations must prove useless and futile.

WATER FOR INFANTS.—Anyone who has ever noticed the avidity with which a fretful, sick infant drinks water and marks the early abatement of febrile and other symptoms, will be convinced that water as a beverage, a quencher of thirst, a physiological necessity in fact, should not be denied to the helpless member of society.—*N. Y. Medical Record*.

Passing Events.

The Press this week gives its readers many extra pages of interesting matter. Our annual mining review, replete with statistics and information for reference, gives the results of the year's work in the different mining States and Territories. It has been compiled with care and is worthy of perusal by all interested in mining affairs.

We give, also in the form of an additional supplement, the complete debris decision, just rendered, in order that our mining readers may study all the legal points brought against the hydraulic mining industry by the Judges of the Court. The decision is a very lengthy one, but no abstract of it would be satisfactory to those whose interests it affects.

Bright sunshine prevails in these latitudes, to the regret of most Californians, for fears are entertained of a dry winter. Still there is plenty of time yet for an abundant rainfall, and the late rains seem to do great deal of good. To those who have formerly worked hydraulic mines a dry season was unfortunate, but this year the lack of water, should there be a scarcity, will make no difference, as few hydraulic mines will be worked after the old fashion.

MINING IN 1883.

A Review of Operations and Results.

A Summary of Important Doings in the Mining Regions Last Year.

Although within the past year there have been no unusual "booms" or mining excitements which have attracted the special attention of the mining community, there have been many local strikes of importance and numerous gratifying developments in old mines, which we have noted in the Press at the time. The year has been very fairly prosperous, from the miners' point of view, although the aggregate productions of the precious metal has fallen a couple of millions short of what it did the previous year. It may be stated as a gratifying fact that with each year's advancement the public becomes more and more imbued with a knowledge of the importance of the mining industry of the nation, which is more generally recognized as a legitimate factor of our national advancement than formerly. In the newer regions the spirit of speculation and stock-dealing prevails, more or less, as it has elsewhere when the country was being opened. Exaggerated values are apt to be fixed to properties in new camps; so that it is not by any means the case that the newly opened sections are the most prosperous.

The principal interest during the past year has been directed toward Idaho and Montana, and Utah has had a good share of attention as well. In California the doubt as to the result of the debris trial has kept hydraulic mining back. To this subject we refer elsewhere in full. Nevada has had a dull year, and the failure to find any bonanza on the Comstock has discouraged many. Arizona is going ahead on a pretty firm basis. New Mexico is expected to do much better this year than last. Oregon and Washington remain about the same, and Colorado still leads in bullion product, California being second.

The Bullion Product.

Notwithstanding all the "booms" and excitements and rushes, the extensive advertising, the wonderful statements, reported rich strikes, "second Comstocks," and all the similar things of which we hear during the year, it is "bullion that talks." At the close of the year when the aggregate shipments of bullion are put together in the form of tables so that comparisons can be made, it does not by any means follow that those places of which we have heard most are the ones that have achieved the best results. Oftentimes the reports are circulated by well-meaning but ignorant persons, or by those who are interested or excited. Persons with little experience in mining are always apt to overestimate or exaggerate. But the end of the year rectifies all these mistakes, and we are able to see where we stand. Perhaps the table we gave last week, and republish below, will tell the tale of the year in the fewest words. It was compiled by Mr. Valentine, General Superintendent of Wells, Fargo & Co. The first is one showing the product of the year 1883:

STATES AND TERRITORIES.	TOTAL.	Ores and Base Bullion by Freight.	Silver Bullion by Express.	Gold Dust and Bullion by Other Conveyances.	Gold Dust and Bullion by Express.
California	\$15,673,314	\$660,209	\$1,474,748	\$669,109	\$13,132,188
Nevada	\$7,771,621	1,749,774	5,924,262	1,097,595	6,626,667
Oregon	\$9,121,021	879,280	8,241,741	879,280	8,360,461
Idaho	63,626	105,200	351	216,326	105,200
Montana	105,200	1,819,700	107,241	4,000,000	1,819,700
Utah	8,807,000	2,480,000	6,327,000	2,480,000	8,807,000
Arizona	7,017,682	4,587,855	2,429,827	2,429,827	7,017,682
New Mexico	24,310,000	17,531,610	6,778,390	6,778,390	24,310,000
Colorado	3,413,510	2,948,900	464,610	464,610	3,413,510
Washington	\$4,182,743	3,845,630	337,113	337,113	\$4,182,743
Wyoming	2,829,000	2,829,000	0	0	2,829,000
Alaska	6,022,010	5,870,545	151,465	151,465	6,022,010
Totals	\$80,313,612	\$23,872,009	\$23,872,009	\$23,872,009	\$80,313,612

This shows the gross yield of 1883 segregated—so as to show the relative percentage of

gold, silver, lead and copper—to be approximately as follows:

Gold, 32.36 per cent.	\$20,230,492
Silver, 23.30 per cent.	47,229,649
Copper, 6.30 per cent.	5,633,921
Lead, 9.04 per cent.	8,163,550
Total	\$80,313,612

The following table, also compiled by Mr. Valentine, is of interest as showing the product for some years back:

Year.	Gold.	Silver.	Copper.	Lead.
1870	\$1,330,000	\$1,330,000	\$1,330,000	\$1,330,000
1871	1,286,000	1,286,000	1,286,000	1,286,000
1872	1,330,000	1,330,000	1,330,000	1,330,000
1873	1,330,000	1,330,000	1,330,000	1,330,000
1874	1,330,000	1,330,000	1,330,000	1,330,000
1875	1,330,000	1,330,000	1,330,000	1,330,000
1876	1,330,000	1,330,000	1,330,000	1,330,000
1877	1,330,000	1,330,000	1,330,000	1,330,000
1878	1,330,000	1,330,000	1,330,000	1,330,000
1879	1,330,000	1,330,000	1,330,000	1,330,000
1880	1,330,000	1,330,000	1,330,000	1,330,000
1881	1,330,000	1,330,000	1,330,000	1,330,000
1882	1,330,000	1,330,000	1,330,000	1,330,000
1883	1,330,000	1,330,000	1,330,000	1,330,000

In reading further on in this review it will be seen that the estimates vary from this in greater or less degree, but these tables have usually been recognized as the nearest correct, and generally accepted as the best basis on which to make comparisons of results. Local authorities are apt to add a few millions more to each State or Territory than Mr. Valentine does.

Leaving figures aside for a moment, it will be of interest to place the States and Territories in their relative positions numerically so that their ranks may be ascertained and compared. The tables are compiled carefully from statistics obtained by the Government when taking the census. The first table shows the rank, however, in 1882, that already given above showing it in 1883 in figures:

RANK OF STATES AND TERRITORIES IN THE PRODUCTION OF GOLD AND SILVER.

Gold.	Silver.	Total.
1. California.	1. Colorado.	1. Colorado.
2. Colorado.	2. Arizona.	2. California.
3. Idaho.	3. Utah.	3. Nevada.
4. Montana.	4. Nevada.	4. Arizona.
5. Nevada.	5. Montana.	5. Utah.
6. Idaho.	6. Idaho.	6. Montana.
7. Arizona.	7. New Mexico.	7. Idaho.
8. Oregon.	8. California.	8. Dakota.
9. Georgia.	9. Dakota.	9. New Mexico.
10. Utah.	10. Oregon.	10. Oregon.
11. North Carolina.	11. North Carolina.	11. Georgia.
12. New Mexico.	12. North Carolina.	12. North Carolina.
13. Alaska.	13. Alaska.	13. Alaska.
14. Washington.	14. Washington.	14. Washington.
15. South Carolina.	15. South Carolina.	15. South Carolina.
16. Virginia.	16. Virginia.	16. Virginia.
17. Wyoming.	17. Wyoming.	17. Wyoming.

RANK OF THE STATES AND TERRITORIES IN THE PRODUCTION OF GOLD AND SILVER IN THE CENSUS YEAR.

Gold.	Silver.	Total.
1. California.	1. Colorado.	1. Colorado.
2. Nevada.	2. Nevada.	2. California.
3. Idaho.	3. Utah.	3. Nevada.
4. Colorado.	4. Montana.	4. Idaho.
5. Arizona.	5. Arizona.	5. Montana.
6. Idaho.	6. California.	6. Dakota.
7. Oregon.	7. Idaho.	7. Arizona.
8. Utah.	8. New Mexico.	8. Idaho.
9. Arizona.	9. Dakota.	9. Oregon.
10. Washington.	10. Michigan.	10. New Mexico.
11. North Carolina.	11. North Carolina.	11. Washington.
12. Georgia.	12. N. Hampshire.	12. North Carolina.
13. New Mexico.	13. Maine.	13. Georgia.
14. Wyoming.	14. Wyoming.	14. N. Hampshire.
15. South Carolina.	15. Michigan.	15. Michigan.
16. New Hampshire.	16. Virginia.	16. Virginia.
17. Virginia.	17. Alaska.	17. South Carolina.
18. Alaska.	18. Tennessee.	18. Maine.
19. Tennessee.	19. Alaska.	19. Tennessee.
20. Alaska.	20. Tennessee.	20. Alaska.
21. Tennessee.	21. Tennessee.	21. Tennessee.
22. Alaska.	22. Alaska.	22. Alaska.

RANK OF THE STATES AND TERRITORIES IN PRODUCTION OF GOLD AND SILVER, PER SQUARE MILE, IN THE CENSUS YEAR.

Gold.	Silver.	Total.
1. California.	1. Colorado.	1. Colorado.
2. Nevada.	2. Nevada.	2. Nevada.
3. Colorado.	3. Colorado.	3. California.
4. Dakota.	4. Utah.	4. Utah.
5. Idaho.	5. Montana.	5. Montana.
6. Montana.	6. California.	6. Idaho.
7. Oregon.	7. Idaho.	7. Dakota.
8. New Mexico.	8. New Mexico.	8. Arizona.
9. North Carolina.	9. North Carolina.	9. Oregon.
10. Washington.	10. Michigan.	10. New Mexico.
11. Arizona.	11. Maine.	11. N. Hampshire.
12. Georgia.	12. Oregon.	12. North Carolina.
13. New Hampshire.	13. North Carolina.	13. Washington.
14. South Carolina.	14. Georgia.	14. Georgia.
15. New Mexico.	15. Michigan.	15. Michigan.
16. Virginia.	16. South Carolina.	16. South Carolina.
17. Maine.	17. Virginia.	17. Virginia.
18. Alaska.	18. Tennessee.	18. Tennessee.
19. Tennessee.	19. Wyoming.	19. Wyoming.
20. Alaska.	20. Tennessee.	20. Tennessee.
21. Tennessee.	21. Tennessee.	21. Tennessee.
22. Alaska.	22. Alaska.	22. Alaska.

The following table is an interesting one as

the relative production of the States and Territories according to population is given in it:

RANK OF THE STATES AND TERRITORIES IN PRODUCTION OF GOLD AND SILVER, PER CAPITA, IN THE CENSUS YEAR.

Gold.	Silver.	Total.
1. Nevada.	1. Nevada.	1. Nevada.
2. Montana.	2. Colorado.	2. Montana.
3. Idaho.	3. Montana.	3. Colorado.
4. Dakota.	4. Arizona.	4. Arizona.
5. California.	5. Utah.	5. Idaho.
6. Idaho.	6. Utah.	6. Utah.
7. Oregon.	7. New Mexico.	7. Dakota.
8. Arizona.	8. California.	8. California.
9. Utah.	9. Dakota.	9. Oregon.
10. Washington.	10. Oregon.	10. New Mexico.
11. N. Hampshire.	11. N. Hampshire.	11. N. Hampshire.
12. Michigan.	12. Michigan.	12. Wyoming.
13. Alaska.	13. Alaska.	13. Alaska.
14. North Carolina.	14. North Carolina.	14. North Carolina.
15. Georgia.	15. N. Hampshire.	15. N. Hampshire.
16. Georgia.	16. Georgia.	16. Georgia.
17. Michigan.	17. Michigan.	17. Michigan.
18. Maine.	18. Maine.	18. Maine.
19. South Carolina.	19. South Carolina.	19. South Carolina.
20. Tennessee.	20. Tennessee.	20. Tennessee.
21. Virginia.	21. Virginia.	21. Virginia.
22. Alaska.	22. Alaska.	22. Alaska.

The question is often asked as to what is the relative rank of the bullion-producing States and Territories per square mile, and by the number of men. The following tables answer these queries:

AVERAGE PRODUCT OF GOLD AND SILVER IN THE CENSUS YEAR PER SQUARE MILE.

STATES AND TERRITORIES.	GOLD.	SILVER.	TOTAL.
Alabama	80.02	80.02	80.02
Alaska	0.01	0.01	0.01
Arizona	1.87	22.45	24.32
California	108.30	7.27	115.57
Colorado	25.93	159.24	185.22
Dakota	22.17	0.48	22.65
Georgia	1.50	0.01	1.51
Idaho	18.45	5.48	23.93
Maine	0.03	0.22	0.25
Michigan	0.44	0.44	0.88
Montana	12.30	19.89	32.25
Nevada	44.16	112.29	156.45
New Hampshire	1.18	1.72	2.90
New Mexico	0.40	3.20	3.60
North Carolina	2.28	0.03	2.31
Oregon	11.48	0.29	11.77
South Carolina	0.05	0.05	0.10
Tennessee	0.05	0.05	0.10
Utah	3.43	55.82	59.25
Virginia	0.22	0.01	0.23
Washington	1.90	0.01	1.91
Wyoming	0.18	0.01	0.19
U. S. (including Alaska)	9.31	11.44	20.75
U. S. (not including Alaska)	11.03	13.65	24.62
U. S. (including only the States and Territories producing gold and silver, with Alaska)	14.68	18.02	32.70
U. S. (including only the States and Territories producing gold and silver and not including Alaska)	19.44	23.94	43.38
Average for Cal., Nev., Utah, Mont., Dakota, Arizona and Idaho.	33.47	42.74	76.21

AVERAGE PRODUCT OF GOLD AND SILVER IN THE CENSUS YEAR, PER CAPITA.

STATES AND TERRITORIES.	GOLD.	SILVER.	TOTAL.
Alabama	80.001	80.001	80.001
Alaska	0.20	0.20	0.40
Arizona	5.24	897.51	902.75
California	19.83	1.33	21.16
Colorado	13.89	85.10	98.99

Total	1,194,826,232 13	27,110,018 83	1,221,936,250 96

Several tables of total bullion product of the United States have been compiled, but the following is that generally accepted:

ESTIMATE OF THE PRODUCTION OF GOLD AND SILVER FROM 1848 TO 1880, INCLUSIVE, BY FISCAL YEARS, AS GENERALLY ACCEPTED IN OFFICIAL REPORTS.

Years.	Gold.	Silver.	Total Gold and Silver.
1848	\$10,000,000	800,000	\$10,800,000
1849	10,000,000	800,000	10,800,000
1850	10,000,000	800,000	10,800,000
1851	10,000,000	800,000	10,800,000
1852	10,000,000	800,000	10,800,000
1853	10,000,000	800,000	10,800,000
1854	10,000,000	800,000	10,800,000
1855	10,000,000	800,000	10,800,000
1856	10,000,000	800,000	10,800,000
1857	10,000,000	800,000	10,800,000
1858	10,000,000	800,000	10,800,000
1859	10,000,000	800,000	10,800,000
1860	10,000,000	800,000	10,800,000
1861	10,000,000	800,000	10,800,000
1862	10,000,000	800,000	10,800,000
1863	10,000,000	800,000	10,800,000
1864	10,000,000	800,000	10,800,000
1865	10,000,000	800,000	10,800,000
1866	10,000,000	800,000	10,800,000
1867	10,000,000	800,000	10,800,000
1868	10,000,000	800,000	10,800,000
1869	10,000,000	800,000	10,800,000
1870	10,000,000	800,000	10,800,000
1871	10,000,000	800,000	10,800,000
1872	10,000,000	800,000	10,800,000
1873	10,000,000	800,000	10,800,000
1874	10,000,000	800,000	10,800,000
1875	10,000,000	800,000	10,800,000
1876	10,000,000	800,000	10,800,000
1877	10,000,000	800,000	10,800,000
1878	10,000,000	800,000	10,800,000
1879	10,000,000	800,000	10,800,000
1880	10,000,000	800,000	10,800,000
Total	\$1,520,041,532	\$490,422,200	\$1,980,463,732

Up to June 30, 1883, the aggregate production of gold in the United States may be stated at \$1,632,364,670, and of silver \$598,083,217, making a grand total of \$2,230,447,887. Reduced to equivalent weight the total gold output has been 78,963,572 troy ounces, or 2,707.4 avoirdupois net tons. The total for silver represents 462,590,469 troy ounces, or 15,860 tons. It will, perhaps, convey little meaning to say that the grand total is in excess of the national debt; but a better conception of the vastness of the amount may be had by considering that all the gold produced in the country up to the present time, if brought together, would suffice to load 271 ordinary freight cars; the silver, supposed in the same way to be collected together as pure bullion, would require 1,586 cars for its transportation. The gold would tax the carrying capacity of a large ocean steamship, while the silver would suffice to form cargoes for a small fleet.

Of course this by no means covers all our mineral products. There are many other things, as copper, lead, iron, salt, borax, mica, manzanese, asbestos, sulphur, asphaltum, zinc, nickel, quicksilver, antimony, platinum and coal, etc., which are not figured in. The total metallic and non-metallic products of the United States in 1882 were valued at \$453,912,406. But in this article we are only considering the precious metal productions.

CALIFORNIA.

Adopting the figures of Jno. J. Valentine, Superintendent of Wells, Fargo & Co.'s Express, California's product of bullion for 1883 was the lowest made in the history of the State, being \$659,184 less than the output of the preceding year, which up to that time had been the lowest made. Without rejecting Mr. Valentine's estimate as being too low, it may be stated that consulting those emanating from the newspaper press and other authorities in the mines, the year's product would appear to have been much larger than estimated by him, amounting to fully \$18,000,000. In verification of this state-

ment we give below the production made last year by the several mining counties of the State, as nearly as we can make out the same, consulting the local sources of information referred to:

County.	Gold.	Silver.	Total.
Alpine	\$10,000	\$20,000	\$30,000
Amador	2,000,000	2,000,000	4,000,000
Butte	500,000	500,000	1,000,000
Calaveras	700,000	700,000	1,400,000
Colusa	3,000	3,000	6,000
Del Norte	250,000	250,000	500,000
El Dorado	700,000	700,000	1,400,000
Fresno	100,000	20,000	120,000
Humboldt	100,000	100,000	200,000
Inyo	200,000	20,000	220,000
Kern	200,000	20,000	220,000
Lassen	150,000	20,000	170,000
Los Angeles	20,000	80,000	100,000
Mariposa	250,000	5,000	255,000
Merced	10,000	10,000	20,000
Monro	1,500,000	400,000	1,900,000
Nevada	3,200,000	10,000	3,210,000
Placer	600,000	900,000	1,500,000
Plumas	1,000,000	1,000,000	2,000,000
Sacramento	300,000	300,000	600,000
San Bernardino	300,000	1,000,000	1,300,000
San Diego	100,000	100,000	200,000
San Luis Obispo	5,000	5,000	10,000
Shasta	300,000	80,000	380,000
Sierra	1,000,000	1,000,000	2,000,000
Siskiyou	700,000	700,000	1,400,000
Stanislaus	75,000	15,000	90,000
Sutro	10,000	10,000	20,000
Tulare	5,000	5,000	10,000
Tuolumne	400,000	400,000	800,000
Yuba	600,000	600,000	1,200,000
Total	\$10,088,000	\$1,870,000	\$12,958,000

We are aware that in some instances much more has been claimed for these counties than they are credited with in the above table, but from all we can gather we incline to the opinion that the figures here given are not much out of the way. We leave certain of the silver-producing counties, which claim to have taken out over two million dollars worth of that metal last year, to reconcile such claim as best they can with the figures of Mr. Valentine, who puts down the entire silver production of the year, ores and base bullion included, at \$1,832,017 for the entire State.

We herewith append a table showing the total and annual bullion production of California, gold and silver included, from 1848 to the end of 1883. As this table has been compiled with great care, the figures given may be accepted as approximately correct—as nearly correct, perhaps, as it is possible to make them, though it may be that we have placed the product of 1883 a little too high.

Year.	Gold.	Silver.	Total.
1848	\$5,000,000	800,000	\$5,800,000
1849	5,000,000	800,000	5,800,000
1850	5,000,000	800,000	5,800,000
1851	5,000,000	800,000	5,800,000
1852	5,000,000	800,000	5,800,000
1853	5,000,000	800,000	5,800,000
1854	5,000,000	800,000	5,800,000
1855	5,000,000	800,000	5,800,000

1883	5,000,000	800,000	5,800,000
Total	\$1,231,850,000	\$20,150,000	\$1,252,000,000

As a general thing, because California has been in the mining business so many years and so little stir or advertising about her mineral resources is done, the other States and Territories are rather inclined to "snub her," and an impression prevails that mining in California is played out. Still, at the end of each year when the results are figured up, California comes up smiling as still No. 1 in the list of gold producers, and No. 2 in the totals. Colorado leads her this year, as last, in the total product; but California comes second, and is about \$6,000,000 ahead of the next below her, which is Montana. In the production of gold California yielded \$13,182,188, while the total gold yield of all was only \$24,823,317. Therefore, California produced several millions in gold more than all the other States and Territories put together.

There have been no "booms," no rushes or speculative spirits in the State during the year. In fact, the mining industry of California has been depressed somewhat in 1883. Yet with all the difficulties she still retains her record

place among the bullion producers of the United States. This is a good proof that honest, legitimate mining pays, and that it is not necessary to get up a great excitement in order to get out bullion. More or less talk about California's decayed mining interests has been indulged in, but, as we have said before, "bullion talks." The new regions of the country have much work before them in building railroads, towns, etc., which we have accomplished; but it took us a long time to do these things. But for the lack of water and the mining debris litigation we should have had several millions more of bullion in 1883.

The decision on this debris question we publish in full in this number of the Press, and under the heading of hydraulic mining refer more fully to the subject. Our bullion will be somewhat decreased by the stoppage of some of these hydraulic mines, but drift and river mining will keep up our surface work, and more or less hydraulic mining will be done also. The quartz mines of the State are being more and more developed and their yield is increasing. New sections have been opened within the past few years which are now producing steadily, and our quartz interests may be said to be in good condition. We have from week to week during the year devoted a large part of the space in our mining summary to the current news concerning California mines, so it is not necessary now to go very much into detail concerning our various districts.

California produces some considerable copper, though her product in this is insignificant as compared with other regions.

Of borax, however, there is a large production. Up to June, 1883, this State had produced 17,857,980 pounds of borax. Of all of California's product 15,625,732 pounds were produced by the San Bernardino Borax Mining Co. The cost of production varies materially. The State Mining Bureau has issued a monograph on this subject by H. G. Hanks, which goes into the borax business at great length, giving yield, processes, points of occurrence, etc.

California is also a large producer of salt. There are some 25 companies operating, producing about 30,000 tons a year. Our asphaltum, lead, sulphur, manganese, chrome, and a number of such products greatly swell our mining yield.

Until within the past few years California has produced no iron, but now it has one mine at Hotelling, near Clipper Gap, Placer Co., owned by the California Iron and Steel Co. The mine produced 4,500 tons of iron in 1881. In 1882 990 tons were made when the works burned down. The works were rebuilt, and have been in operation since May, 1883. From that time to December 2d the product was 7,416 tons, all of which is consumed here. The product of iron from these furnaces is of a superior quality, and now has preference over any brought to the coast. The Central Pacific Railroad Company uses it quite extensively, taking regularly 200 tons a month for making car wheels and other work.

Of the present operations of the company, the Grass Valley Union says: The operations of the iron company at Hotelling are growing in importance, and are being conducted on an extensive scale. The number of men engaged at the furnace, mining out the ore, burning charcoal, cutting timber, teaming, and in other ways connected with the business, number well up towards 300 men. Teams are constantly engaged in hauling pig iron to the railroad station at Clipper Gap, two and one-half miles distant, where between 7,000 and 8,000 tons are now awaiting shipment. These huge piles of metal never fail to attract the attention of passengers on passing railroad trains, who by this means gain some idea of the importance of this new industry in the foothills. A survey of a railroad route has been made between Clipper Gap and Hotelling; but whether the road is soon to be undertaken is not yet announced, but that it will become a necessary adjunct to the business there is no doubt. The company has recently bought large tracts of land from the Central Pacific railroad for the purpose of obtaining wood to burn for charcoal, and has also bought a great deal of standing timber from the individual owners on both sides of Bear river. The consumption of timber for the kilns is enormous, all kinds being used in making charcoal, and in a few years the country around Hotelling for miles will be divested of its timber. The Judson Manufacturing Co. use the product at their

works, and our local foundries make use of it also.

Hydraulic Mining.

For this branch of mining the past has been an unfortunate year in several respects; some of the large companies operating in the more central mining counties have been estopped running by injunctions issued from the courts or by scarcity of water, there having been but little threats of such proceedings. Then a general snow on the mountains the preceding winter, made for this class of miners a short working season all over the State, the run, as compared with ordinary years, having been abridged fully one-third. So far, the present winter, this water dearth has been continued, the hydraulic miners—where permitted to go on—having up to this time done very little. But with all these interferences, drawbacks and delays the condition of this industry, though a little discouraging, is by no means desperate. We see no reason why the hydraulic companies, who have been restrained from running by order of the courts, should not go on and build their retaining dams, and then resume operations, wherever well made dams will so far abate the evil complained of as to justify them in doing so. Then there is the chance of Judge Sawyer's decision being reversed, or at least essentially modified, by the higher courts, relieving, somewhat, the stringency of the present situation. The hydraulic miners of California have brought this business to a high state of perfection, and if suffered to go on unimpeded, would be able to render it not only largely productive, but fairly remunerative hereafter. While labor has been so economized as to greatly reduce current expenses, such gold-saving contrivances have been introduced as avoid much of the waste formerly complained of. To advance this industry and place it on a sound footing has cost much time, money and patient labor; and all will agree that it should not at this stage in its history be crippled without good cause. California can ill afford to have any of her wealth-producing factors even partially suppressed, nor can the contributions from these mines well be spared from the gold stock of the country without great hardship.

The policy pursued by our courts towards the hydraulic mines finds no precedent elsewhere. Other countries possessing auriferous deposits capable of being profitably worked by the hydraulic method, encourage capitalists to open them up and work them to the fullest extent. Investors having engaged in enterprises of this kind in Australia, Central and South America, Africa and other parts of the world, are now in search of California miners to come and take charge of them. These calls emanate from New York, Boston, Chicago and other cities, both in the interior and on the Atlantic seaboard, as well, also, as from London, Paris and other places on the Continent of Europe, showing the high estimation in which this class of mines and miners is held elsewhere.

From Henry G. Hauks, of the State Mining Bureau, we learn that applications have been made to that institution for suitable parties to go to Australia and South America to take charge of hydraulic operations, those in Australia to be conducted for washing both gold and tin. Already a number of our most capable miners have left on missions of this kind. Mr. D. Crittenden recently took his departure from San Francisco for the Transvaal Republic, South Africa, where he goes in the service of an English company who have large interests there. A heavy order from this company for pipes, giants, and other hydraulic apparatus, is now being filled in this city. Mr. Crittenden is accompanied by Messrs. McClelland and Bradshaw, both experienced hydraulic miners on this coast. Mr. Joseph Messerer has for some time past been in Chili, acting in the capacity of superintendent for a hydraulic mining company there. Frederick F. Birge is at present in the United States of Colombia, South America, inspecting hydraulic gravel deposits for an Eastern company. Mr. Birge is a young man of fine character and first class business capacities, being withal a thoroughly trained miner. His selection for the work entrusted to his care is fortunate for his employers. Henry L. Perkins, formerly Superintendent of the North Bloomfield mine, and Thomas Mein, both of whom have had a long experience in our mines, are in Venezuela.

There may be, and probably are, other California miners who have gone abroad in the

Tybo, another of these Nevada camps, which after a successful career suffered partial eclipse. It has also been resurrected to a new life. Valuable ore bodies have lately been developed in the mines there, both old and new. The smelter erected by an Eastern company in the Montezuma district, but which was unable to run in consequence of a sudden and unexpected failure of water, having been removed to another locality, will soon commence operations with the assurance of turning out large quantities of lead-silver bullion. And so, all over the State we hear of

renewed activity or the note of preparation, indicating that Nevada is about to resume her onward march after so long a period of comparative inaction.

Merrimac District.

Merrimac district, near Tuscarora, and better known perhaps as Lone Mountain, is in Elko county. For the facts from this district we are indebted to a correspondent who writes us as follows:

Editor's Press:—As you intend publishing a summary of mining operations during 1883, I send you a few facts concerning Merrimac district. The Merrimac mine has two shafts, each 75 feet deep; also one of 30 feet, all of which show large quantities of good ore. The ore will average 20 per cent copper, and 30 ounces silver, of which there are about 200 tons on the dumps. The ledge is 10 to 15 feet wide with four foot pay ore. The Amy Western has 135 feet of work done, and shows a large body of rich carbonate copper ore averaging 27 per cent copper. There are about 50 tons on the dumps. On the Copper King over 100 feet of work has been done, and there is a large quantity of ore in sight, carrying 25 per cent copper and 30 ounces silver per ton. On the same claim there is a lead carbonate ledge 10 feet wide averaging \$43 per ton in silver and gold. The Relief Mine has 135 feet of workings with a ledge two feet wide carrying ore averaging 24 per cent copper and 50 dollars in silver and gold.

The Melbourne Mine has a ledge 30 feet wide, averaging 14 per cent copper. The shaft is down about 50 feet and there are 100 tons of ore in the dumps. The Copper Queen has ore going as high as five per cent copper, and 16 ounces of silver per ton. The shaft on this claim is 55 feet deep. The above are the leading mines of the district, but in addition there are about 20 very promising locations. A water jacket smelter will probably be erected early this spring, when we anticipate a lively time in Merrimac.

S. G. WESTON.

The famous Consolidated Virginia mine, on the Comstock, has not done much the last year. The annual meeting of the company was held a few days ago. The explorations during the past year have been much interfered with by water encountered in the main south drifts of the 2500 and 2700 levels. This water, however, has shown a material decrease in amount during the last few months.

IDAHO.

More attention has been turned to Idaho during the past year than for many years past. In fact, for two or three seasons the mining interests of this Territory have attracted great attention. Up to that time the growth of the industry was slow, and was much retarded by the bad reputation many of the mines obtained through the manipulation of unscrupulous operators in the San Francisco stock market. Means of communication have been had through the Territory. For the past three or four years, however, Eastern Idaho, from the Salmon river on the north to the lava beds on the south, has been teeming with prospectors and miners; thousands of locations have been made on the Salmon river. Yankee Fork, Sawtooth Range, and Lower Wood River, Little Wood River and Little Lost River mines have been opened and worked, mills and smelting furnaces put up, and bullion is being rapidly produced. Railroads are opening the way to the regions, and many old districts are being worked, while new ones are being opened. The coming season will see a great rush to the Coeur d'Alene placers, which were only known late in the fall. The mining excitement of the year will be in Idaho. In 1882 the product was, according to Mint statistics, \$8,500,000, divided as follows by counties:

County.	Amount.
Alturas.....	\$945,000
Boise.....	310,000
Cassia.....	25,000
Custer.....	1,250,000
Idaho.....	240,000
Lehihi.....	210,000
Nex Perces.....	5,000
Oncida.....	35,000
Owyhee.....	430,000
Shoshone.....	50,000
Total.....	\$3,500,000

Of this total \$1,500,000 was gold, the rest in silver. Idaho is now a great lead producer. Numerous large deposits have been found in the Wood river and adjacent regions, and a number of furnaces have been built. Idaho was supposed to have produced 5,000 tons of lead in 1882. For Idaho, the past year has been marked by many events bringing prosperity with them and the certain promise of a grand future. The Territory, so long isolated and almost unknown, has at length emerged from obscurity, and several thousands of industrious

and enterprising citizens have been added to the permanent population. The inevitable railroad has come, giving rapid and easy communication with the outside world, and bringing many changes, most of which are fraught with immediate good, and all of which must be accepted with well-grounded hope of ultimate benefit. Several good descriptive articles of the Idaho mines appeared in the Salt Lake Tribune of recent date. In the development of the Wood River country the Philadelphia Mining and Smelting Co. has taken an important part. They have very fine works in a central location. The Wood River mining country begins below Bellevue and extends northward to the head of Big Wood river, fifty miles above. Ketchum is located seventeen miles above Bellevue, and taking the mining district at present operated, is almost central to it. To the west, mines extend over to Little Smoky, a distance of twenty-five miles, while to the east, south and north, mines are tributary about the same distance. Just above Ketchum Warm Spring creek enters Wood river.

The Philadelphia Mining and Smelting Co. is composed of men connected with the oil trade, and the officers are E. J. Mathews, President; James M. Rhodes, Vice-President, with a board of directors. G. B. Moulton is the Superintendent of the company in Idaho. Following is a statement of tonnage for the season of 1883: Ore melted, net, 7,550 tons; of this they received from Hailey, 2,380 tons, making output of mines in this immediate vicinity, 5,170 tons; product in bullion, 3,200 tons, with a gross value of \$960,000. It is a notable fact the ores smelted since the works were started in the fall of 1881, have been so rich as to average 149 ounces silver, and paid the seller an average of \$102 per ton. The ores came from eighty-five mines.

Wood River Region.

The country known as Wood River, Idaho, has been prominently before the public for three years or more, and is pretty well known in mining circles; and yet the stories of the marvelous riches of the country are not greater than the reality. Covering a country 100 miles square, there is dispersed immense riches in silver, lead, copper, gold and vast bodies of timber, all of which will yield great wealth to the world. The country is most easily reached from the south through Bellevue, the first and Pioneer town of the district. It is impossible to even enumerate all the mines in the region, and only a few of them can be mentioned. The Minnie Moore employs 22 men; the Queen of the Hill, owned by the Bellevue, M. Co., employs 15 men; the Overland, Humboldt, Monitor, Monday and Penobscot. At Bullion is the Bullion mine, owned by the Wood River Co; Mayflower, Jay Gould; O. K. Eureka, Bates and Boyd Group, Idahoan; then there are the Montana, Mount View, Davitt, Emma and others. But to go through all the mines and enumerate the three or four hundred in Wood River worthy of notice, requires too much space.

From May 26th to November 1st, 1883, there was shipped from Hailey 5,195,100 pounds of bullion and 4,581,900 pounds of ore. Nearly one-third of these shipments of five months and five days were made in October, and the two months of November and December, if added, would bring the total up to about 16,000,000 pounds for the season, while the shipments of ore from Bellevue would add considerable more.

The mines being operated near by and contributing to Ketchum are in the following districts, and distant as follows: It is 12 miles to Hailey, 17 to Bellevue, near which are numerous properties shipping to the Philadelphia smelters; 19 to the great Bullion mines, about the same to the Narrow Ganges, 28 to Galena, 12 to Boyle Mountain, 7 to West Fork mines, 5 to the Lake Creek mine, 6 to mines on Trail creek, 4 to the Elkhorn and Baltimore group, 8 to Green Horn Gulch, 7 to East Fork mines, the North Star, etc., 20 to the iron mines at the head of East Fork, and 60 or 70 to Challis and the mines near there; 12 to 15 miles up Wood river is the Boulder district, where rich gold has been lately discovered in a porphyry belt running through the country, and traceable 15 or 20 miles. This latter discovery was made only late last fall, and promises to open up a new field entirely in Wood River mining.

Little Smoky is one of the leading districts,

and has many promising mines, such as the Smoky Bullion, Ophir, Providence, Blake, First Chance, Buckeye, Fisher, Fourth of July and Pennsylvania. There are several other very promising prospects within a radius of two miles of the Smoky Bullion Co's. mill, and all tributary to the same: the Alturas, Black Tail, Summit, Monarch, Bonanza, California, Illinois and others. About two miles north of the Fourth of July group of mines, on the extreme headwaters of Warm Springs creek and the Smokies, are located the Lone Pine, Deer Trail, Hubson, Maud S., Magnolia and Maggie Campbell, a series of claims owned by Robert Campbell, Thos. Fenton and others. Among others are the Scott and Cobert, Isabella, Carrie Leonard, Tippecanoe, Silver Star, Salamander, King of the West, Winterset and Gaelic.

The Coeur d'Alene Country.

The older mining regions of the Territory, which have been in the shade for some time back, are still working, and are improving too. But it is with the newer ones we are most interested; and of these at present most attention is being turned to the Coeur d'Alene region. Hundreds are now endeavoring to get in over the rough roads and through the snow. They are forming rendezvous along the road so as to get in as early as possible next spring. Along Pritchard and Eagle creeks locations have been made, and more or less work done for an extent of fifteen miles. Pritchard creek runs due east and west for a distance of 25 miles. Eagle creek runs north and south, being 12 miles long and having its source toward Herron Siding. The Bitter-root range of mountains extends almost due north, butting against the Coeur d'Alenes, which turn abruptly to the west. Almost the entire district is covered with timber, mountains and all. Although the country is wild and rough, the mountains do not present the extremely rugged and rocky aspect so noticeable in many mountain regions. At present very few protruding rocks are shown by the upheaval. A gravel formation extends over the mountains to the tops. It is very probable that good quartz mines will be found along the gulches that put into these mountains from the principal creeks. Quartz has already been found along Pritchard creek from the bank to a mile back. The heads of the gulches have not yet been prospected, but the probabilities are that rich mines will be found there. In the broader basins of the principal creeks above the bed rock loose gravel or wash, resembling tailings, constitute the deposit. No clay or like sediment is found in the gravel, and very little sand. The gravel is not coarse, but rather fine. There are few boulders that cannot be easily handled. The bedrock is found at a depth of from one to fifteen feet from the surface. No deep channel of the creek has ever been found, and the miners expect when they do find it to strike good pay gravel. The indications are that it will be in richness much like Williams' creek, Caribou. The rim rock of Pritchard creek resembles greatly that of the former placer mining section.

The only feasible and practicable route to get to the mines, either now or in the spring, is via Rathdrum. The Herron Siding trail is very impracticable and most of the year is impassable. From Rathdrum, by way of Coeur d'Alene City, the topography of the country is such that a greatly superior route is afforded. If the visitor could take a direct line from Rathdrum to the mines he would only be required to travel 45 miles; the route he is obliged to go however, because of formidable mountain ranges, is over 100 miles.

Three grades of gold have been found in the mining district, averaging about \$17, or slightly above, per ounce. This is mainly what is called fine coarse gold, being found in the interstices of the slate and slate bed rock. Some very large nuggets have been found also. It is fully expected that some 25,000 or 30,000 men will go to these new mines in the spring. It must be remembered that quartz mines have been found in the region as well as placers, and more ledges will undoubtedly be discovered when the prospectors can work.

Living is high, cabins are scarce, and those who endure the excessive cold and fatigue of the trail must needs have a long pocket-book to last them till spring. Nothing can be done anyway, and they will be far more comfortable to remain at home attending to business.

UTAH.

Utah has probably shown as much advancement in her mineral development in the past year as any of the Territories or States. The bullion product evinces a very satisfactory increase, and is of greater proportionate percentage than that of any of the other regions. Three or four of the districts are yielding in a wonderful manner, and several of the mines are now world renowned. With such mines as the Ontario, Horn Silver, Eureka, Cave and Crescent, and a host of other steady bullion producers, the Territory is in a position to prove the value of its mineral resources. Salt Lake is growing more and more as a mining center. There is yet a large extent of undeveloped ground in Utah, which will in the future greatly add to the wealth of the world when the region is more fully opened.

Perhaps no better indication of the past year's work could be given than the table of bullion yield from Wells, Fargo & Co.'s statistics which we give in our supplement, opposite page 61.

These figures speak for themselves. Of course it would be impossible to give in a comparatively brief article like this a full review of all the mining districts and mines in Utah. The Salt Lake Tribune, however, published on the 1st inst. a very complete number, giving detailed information from all the camps, in very creditable shape; and from the various letters we have condensed sufficient to give a good general idea of what has been done during the year:

Little Cottonwood is one of the oldest districts of Utah, but it still holds its place among the productive ones. The famous Emma mine is still being worked (by a new company), and very actively, too. Moreover, the old dump which has been worked over two or three times, continues to yield good pay by water concentration. The Joab Lawrence Company, working the Vallejo and North Star mines, have been shipping regularly during the season, and have lately opened up a remarkable body of rich ore. The City Rock group, comprising the City Rock, King of the West, Utah and several other adjacent locations, continues to hold its place at the head of the ore-producing properties, and, in the way of development, surpasses all others combined. Among other prosperous claims are the Gardner-Morrell Co., Grizzly Flat Co., Buffalo Tunnel, Superior, La Pinta, Katie, Lonisa, Sells, Jones & Paddock, Lexington, Norfolk and Boston (owned by Chambers, Colbath, Whipple, Delano and others); Pernvian, owned by James Wall; Moltke, by Henry Wagner; Romulus Tunnel, owned by Albert Thomas and F. Rettrick; Cambrian, by Thomas and Williams; Equitable Tunnel, Alta, owned by C. M. Sukler; Goodrich Tunnel, Nabob, Buckland Tunnel, James Wilson.

Marysville is another section of Utah where there are many mines, among them the Occident, Moore, Silver Hill, Silver Fleece, Fillmore, Elsie, Bully Boy, Webster, Copper Belt, Sonora, Beecher, Cady Stanton, Eucalyptus, Chattanooga, Ferris, Star Mine, Silver Chief, Giles, Red Jacket, Sunday, Ruby and Mattie Rush.

In Frisco district is the famous Horn Silver mine, which has earned an enviable reputation as a bullion producer. The mine, during 1883, shipped from 100 to 150 tons of ore a day to the company's smelters at Franklyn. Developments have gone on steadily during the past twelve months. Major Goodspeed, an expert who has a national reputation, made a personal inspection of the mine during the month of November, and after actual measurement he computed that there were 315,000 tons of ore in sight between the fourth and seventh levels. Active preparations are now being made to sink another working shaft and to put up more powerful machinery. The ledge is as strong on the lowest as it was on the upper levels. Frisco, which is the main mining camp of Southern Utah, is the headquarters of the Frisco Mining and Smelting Co., which has a 50-ton smelter and a dry concentrating mill. The Cactus and Comet mines at Copper Gulch, three miles from Frisco, are in process of development. The latter mine was bought last year by French capitalists.

Beaver Lake district adjoins the San Francisco district. It is only within the last few months that this district has begun to attract the attention of prospectors and mining men

throughout the Territory. The discovery of the Blue Bird, the White Mountain and other valuable finds, which have been made the present year, has created quite a stir among mining men on the coast.

Star district is situated one mile east from the main range, and four miles southwest of the Utah Central Railroad. Among the mines are the Vicksburg, owned by B. Tathan; Minnesota, No. 2, by J. H. Cook and C. T. Martin; Golden Era, by A. G. Campbell and D. H. Cook; Vulcan, by A. G. Campbell and Wm. Sloan; Oneida, by W. S. Seals and I. T. Clark; Cortez and Esmeralda, by C. L. Woodhouse; Monte Christo, by P. L. Orth and I. C. Berkby; Chief, by Forgie Bros.; and the Aerial, by I. H. Cook. All these mines, except the patented ones, have been worked this year.

Big Cottonwood district, which possesses many good mines and prospects, has been quiet for a number of years. Last season a number of new strikes were made, and as a result renewed interest was taken in the district. Prospects which had remained idle for months and years were started up, and every miner considered he had a bonanza at his cabin door. A large amount of money has been expended in the development of the Big Cottonwood mines, and a large amount taken from its rough and rugged hills. More remains awaiting the strong arm of the miner. Among the principal mines are the Reed and Benson, Maxfield, Silver Mountain, Carbonate, Chester and Exchange.

Park City has a reputation for its excellent mineral belt and the amount of bullion produced by its mines. The chief mine of the camp, and one of the best on the continent, is the famous Ontario. The mine is perfectly outfitted with the very best of mining and metallurgical appliances. Among the improvements last year was the drain tunnel 5,763 feet long, which taps the mine in the 600 level. It cost from \$25 to \$30 per foot, but will save \$100,000 a year. There are 300 men in the mine, under Col. Chambers and his assistants, Neal Gilles, James Kirwin, Keith, Foote and Correll. The 40-stamp mill has pounded out \$14,000,000 since it was built in 1877; and this year produced \$2,000,000 of refined bullion. There are 3,000 tons of ore at the mill. Among other mines are the Parley's Park, owned by the Standard Oil Co.; the Empire, Daly group, Black Diamond, Fairview, Crescent, Apex, Silver Key, Roaring Lion (by S. Levy), Council Bluffs, Uintah, Minnie Wheeler, Union, Keystone, Barry Con. (by Lawrence, Treweek, Reed and Barry); Bonhomme, Samson and Woodside. In Pinon canyon are several promising mines, among them the Glenco, owned by Col. Shaughnessy, Fourth of July (by Cook, Shears, Cupel and Brennan); Wasatch East and Homestake. In McHenry gulch are the McHenry mine, Hawkeye (by George Black, John Hughes and others); the Hawkeye, Lowell and Boulder. On White Pine Ridge are the White Pine, Flagstaff, Pioneer (superintended by George Pierson), Minnesota, Utah, James Bonanza and Badger.

In Clifton district not much work was done last year, and what there was the prospectors did. The following properties were worked during the year: Confederate, Holy Terror, I. O. U. (owned by F. J. Kearney); a mica mine owned by W. R. Sheldon, the Hawkeye, John Randolph, Wilson, Pinte and Gold Hill.

Of the Stockton mines it may be said there is a bright outlook, and last year there was a good deal of money produced from old mines under lease. The Honorable Mining Co. (C. E. Mitchener, Supt.) works 25 men, and ships 25 to 100 tons of ore a month. Among others are the Calumet, owned by F. Auerbach and L. Kerckhoff of Salt Lake; King, by W. S. Godbe and B. Hampton, and River owned by G. J. Spitz. The following mines produced more or less ore under leases: Lion, Legal Tender, Rent Valley, Muscatine, Catherine, East Argent, Black Diamond, and King No. 2, Dry Canyon, has turned out considerable money from leased mines. From Ophir district quantities of ore have been shipped.

Bingham, or West Mountain district, one of the oldest in Utah, was worked as a placer camp for a long time, but finally silver-lead ledges were discovered which have since yielded millions. Recent developments are serving to instill new energy into the people. The district is divided into Main Bingham, Carr Fork, Muddy, Highland, Butterfield Canyon, Copper Gulch and Black Jack. Among the many mines are the Winnemucca, Dixon, under lease to Watson & Stanchfield, Trawauke, owned by Goldberg and Shaughnessy, Markham, Nast, owned by Auerbach Bros., Stewart No. 1, (the leading gold quartz mine of the camp), Stewart No. 2, Sacred, Last Chance (S. Bamberger Supt.), True Fissure, Venus and Jupiter, Sunset, Wide West, Elephant, Sunset. At Highland are the J. P., the Alameda, Alladin, Neptune, Jordau, Ashland, Old Utah, Silver Shield, Silver Crown, Hibernia and St. James; the Old Telegraph, a famous mine, is being worked under lease; the Brooklyn (J. J. O'Toole Supt.); the Yosemite is yielding 220 tons a month; the Lead mine, Wasatch and Mayflower are all flourishing mines.

In American Fork they are opening up new mines and developing old ones. The principal mines are: The Miller Mining and Smelting Company mines, comprising the Miller, Wyoming, Alpine, Tonto, Tom Green, Miller West Extension, Sarchfield and Aspinwall, developed by the Carr, Lady Annie, Emeline, Alpine, Wyoming and Mormon tunnels; Mary Ellen,

Live Yankee, Live Yankee First West Extension, Powers and Quartzite, owned by Messrs. Delany, Matt, Cullen, A. Campbell, Burk and O'Brien of Boston and Salt Lake; Silver Bell, Mono, Eudora, First Chance, Henrietta and Red Cloud, owned by the Silver Bell Mining Company, Michael Shaughnessy, President; Russel, Germania and Excelsior; Lady Annie, La Belle, Bredemeyer, Cologne, and Sparrow Hawk, bonded by the Utah Con. Co.; Lady Katherine and Rudolph, bonded by the Utah Con. Co.; Little Cloud or Mountain Lion, owned by Frank Birk, Watson, Chadwick and Co.; Amaryllis and Non-Compromise, owned by the Comstock Co., L. E. Holden, President; Wild Dutchman, Lost Maid, Austin, Cloudburst, Sierra, Echo, Plum, Atlas, Missouri, Orphan, Caribon, Great Western, Rosebud, Pittsburg, War Eagle, etc.

The above mines of American Fork and Silver Lake have produced in the past tens of thousands of tons of good, high-grade ore, and are certainly capable of producing immense quantities more of the best quality. The districts contain the Sultana Smelting Works (three shaft and one reverberatory furnace), fifty charcoal and limekilns, and five saw-mills. The towering mountains are covered with magnificent red and white-pine timber; streams of crystal water rush all the year round from the mountains, giving the finest water power everywhere throughout the districts for any and all purposes connected with and beneficial to mining and the concentration and reduction of ores.

Central Utah is a region embracing some 700 miles of mineral land, and within this area are many mining districts. Nebo district is in limestone. The most prominent mining claims here are owned by Wm. Jennings and Sons and Simon Bamberger & Brothers, of Salt Lake City. The district is well timbered and watered, is near the line of the Utah Central Railway, and in the near future may be expected to rank with the Cottonwoods as one of the lead-silver producing centers of Utah.

The Tintic Mining District comprises an area of something over 100 square miles of the mineralized portion of this mountain range, and in point of development takes precedence of all other mining districts of Central Utah. It is distant from Salt Lake City about 84 miles. The initiative mining is now being done at Eureka Hill. The Eureka Hill Mining Co. have several mines, all at work. Among the prominent mines are the Bullion and Beck, owned by John Beck; Cornucopia, owned by Patric Cusick, of Eureka; Mono, by James Robbins; Northern Spy, owned by the Tintic M. Co., a Chicago organization. The iron mines at Silver City shipped 18,000 tons of iron ore in 1883. Among the mines are the Park, Sunbeam and Elmer Ray, owned by D. S. Dana; the Julian Lane; the Rose of Tintic, Star of India, Josephine and others, owned by the Tintic M. Co.; the Mammoth, the greatest mining property of Tintic; Maxwell Copperopolis, the American Eagle and Crisman Mammoth.

In West Tintic District are the Satan, January, Enid, Shoo Fly, Jersey Lily, Fairview, and many others partly opened. In Desert District are the Red Bird, Copper Star and Camelia. In Oasis District is the Iron Duke. Dugway and Detroit Districts each have many promising mines.

MONTANA.

Montana produced nearly ten millions of dollars last year, thus bringing herself forward to the third place in the bullion-producing regions, eclipsing Arizona, Utah and Nevada, and coming within about six millions of California. This is a record to be proud of. In fact, Montana and Idaho are the only two Territories which show an increase of bullion product for the past year. Montana's relative position as a producer we have referred to in another part of the review more fully. There is some discrepancy in the totals as estimated by the Mint Director, Wells, Fargo & Co., and local authorities, the latter usually placing the figures the highest. The principal mines are those around Butte, which we refer to further on more in detail. Around Helena the placers are pretty well exhausted. The diggings that are being operated are confined mainly to the head of Oro Fino and Grizzly gulches, both tributary to Last Chance gulch.

A Comprehensive Letter.

"The mining interests of Montana are now attracting much attention from men interested in the production of silver, copper and gold. The variety, permanence and magnitude of its resources are but now beginning to be understood; and though the Territory is not indulging in the fictitious and hurtful excitement of a boom, the amount and value of its production are sufficiently important to command the attention of moneyed men both in the East and West."

The above is an expression of opinion made by J. B. Read, the Montana Commissioner, to the Denver Exposition last year, in answer to a question concerning the Territory. It is a brief statement of the present condition. For the following details we are indebted to a correspondent of the Press who is well posted on Montana affairs, and it will be read with interest here in view of the fact that many California capitalists, among them Haggins and Tevis, have lately made heavy investments in that section of the great mineral belt of the

continent. This belt extends north and south through almost the central part of the Territory, covering a very extensive area and embracing the counties of Beaverhead, Madison, Deer Lodge, Silver Bow, Lewis, Clarke and Meagher, with some good mines in isolated localities. In Beaverhead are some very valuable properties, prominent among which are those of the Hecla Company paying regular monthly dividends of \$15,000. The dividends last year amounted to \$180,000. These mines, thoroughly developed and exposing fine bodies of silver-lead ore, are located at Glendale and are owned in Indiana, Governor Hendricks being among the fortunate. Other districts in the county are also shipping considerable ore, particularly the Tidal Wave district.

In Madison county, where the famous Alder Gulch is located—a gulch that has produced \$60,000,000 in gold dust—quartz operations are quite active, and a splendid record is being made. In Deer Lodge county are the Phillipsburg and Cable districts. In the former the Granite Mountain mine shows five feet of \$300 ore at a depth of 300 feet. It is the richest silver mine in Montana, and in a twenty-stamp mill is producing over \$60,000 monthly in bullion 950 fine. In the Cable district the famous Cable gold mine is being worked. A tunnel 2,500 feet long taps the ledge 300 feet deep and crosscuts show the vein of pay ore to be 40 feet wide. From the face of the tunnel drifts have been run 100 feet east and west and the ore body retains its width. A thirty-stamp mill has lately been erected, in which it is the intention of the company to beat seventy tons of ore daily. This amount of ore, which will average \$40 per ton, can be extracted with the greatest ease and a monthly productive capacity of \$80,000 may be considered a very conservative estimate. The property is owned in Des Moines, Iowa, and is regarded as the richest gold mine in Montana. A million dollars would not buy it.

In Lewis and Clarke counties the Gregory, Gloster, Alta Montana group and the Drum Lummou are the best developed, though there are doubtless many unexplored mines there of equal merit. The two first mentioned are owned in Boston, and are shipping regularly. The Gregory is a silver-lead mine, and the Gloster has an extensive run of pay gold ore. By far the most valuable and profitable property in the county, however, is the Drum Lummou, for which an English syndicate last spring paid \$1,500,000. At a depth of 150 feet, the Drum Lummou shows a pay ore body of the remarkable width of 80 feet. From wall to wall its average assay value is \$50, one-half silver and the remainder gold. By experienced mining men it is considered the most remarkable silver gold ore body in the world. It is now being thoroughly explored under the able management of George Atwood. The immense vein has been or soon will be tapped by a tunnel at a depth of 300 feet. The progress of development will be watched with deep interest.

In Northern Montana, the new districts of Barker, Maginnis and Maiden are receiving much attention and contain some very promising mines, both silver and gold. Several mills and smelters are in active operation on good ore, and the erection of others is contemplated. The Clarks Fork mines in Gallatin county, among them the Jay Cooke, Great Republic and others, are being developed with very encouraging results and are rapidly coming to the front.

Butte.

The great mining center of the Territory is Butte, situated in Silver Bow county. In the amount of its production, Butte ranks next to Leadville among the great mining camps of the world. Its output last year was \$7,200,000 in silver, copper and gold, and the facilities for treating ore are being constantly increased. The leading mines of Butte are developed, paying properties, and, while not remarkable for extreme richness, they are wonderfully productive and undoubtedly permanent. They are true fissures in granite, and generally vary in width from ten to fifty feet. The strike of the veins is east and west, the dip south and the walls, in nearly every case, regular and well defined. The ore lies in shoots, dipping invariably to the west. The ores below the water line in all cases are sulphurets. Water is struck usually at about 50 feet from the surface, but is not too abundant to be readily handled by pumps. The ores are of three varieties, viz: silver, copper and those containing both metals in varying proportions. The first mentioned are worked in dry crushing chloridizing mills, and the others by the smelting process. The average value of the silver ores is \$45 and some gold. The average percentage of the copper ores is perhaps 25, though large amounts of 50 and even 75 per cent copper ores are extracted and shipped to Swansea in a crude state. The copper mattes are transported to the same point, where the silver they contain commands a good price. The average daily shipments of copper ore and matte combined aggregate 150 tons. The amount of silver ores treated in the mills exceeds 300 tons daily. A careful and conservative estimate of the realized value of the product of the district in silver, copper and gold is \$25,000 per day.

Considering the amount of money invested, it may be safely stated that neither Leadville nor any other camp ever before made such a showing. The principal companies' mines and reduction works are as follows:

Anaconda copper shaft 800 feet deep, mine fully developed; amount of ore in sight estimated at

nearly 100,000 tons, shipping regularly copper glance to Swansea; steam hoist cost \$90,000; investment up to present time, about \$1,500,000; owners, Haggins and Tevis; Superintendent, Marcus Daly.

Alice silver shaft, 800 feet deep; daily product of company's mines, 90 tons; two mills in operation, 80 stamps in all; owners, Alice Co.; Superintendent, Wm. E. Hall.

Moulton, silver; shaft 500 feet deep; daily product 40 tons; average value \$38; 40-stamp mill in operation; President of company, W. A. Clark.

Lexington, silver; shaft 500 feet deep; two mills, 75 stamps; monthly produce averages \$105,000; first dividend paid in July was 1,000,000 francs; company organized in Paris, France; Superintendent, A. Wartenweiler.

Silver Bow, silver; shaft from 200 to 400 feet deep; mill, 30 stamps; monthly output \$35,000; President, D. A. Talbot.

Dexter Mill, silver; doing custom work; 15 stamps; wet crushing.

Montana Copper Company; smelter capacity, 100 tons daily; mine (the Colusa) 400 feet deep; copper and silver; product daily, 25 tons of matte; product last year \$1,800,000.

Parrot Company copper smelter, capacity 75 tons; mine 400 feet deep; ore body 12 feet wide; shipments of matte, about 12 tons daily; A. F. Migeon, Superintendent.

Williams, smelter, branch of Argo Works, Denver; capacity, 40 tons daily, to be increased this fall one-third, does custom work at high rates; 10,000 tons of ore on the dump; average value of \$50, matte shipments assay 50 per cent copper and from \$600 to 1,500 in silver; production for 1882, \$864,000—a "bear" estimate.

Bull Company, smelter capacity 60 tons; mine well developed to depth of 400 feet; ore, silver and copper, width of vein from 8 to 24 feet; company lately reorganized; James King, President; matte shipments, 10 tons daily, to be increased.

Liquidator, copper; vein 35 feet wide, all pay; shaft 200 feet deep; company now filling a 4,000 ton contract; mine an extension of Colusa; Superintendent, Wm. McDermott.

Shonbar, silver; shaft 250 feet; pay stock from two to six feet; average product \$20,000 per month; ore output worked in custom mill; ore, a black sulphuret; average value \$160 per ton; owner Chas. S. Warren, et al.

Modoc, copper; shaft 200 feet; two levels run; ore body six feet wide; average value 20 per cent copper; Joel Ransome, Superintendent and owner.

Clear Grit, copper silver; shaft 317 feet deep; shows over 30 feet of good copper ore in lowest level, also assays in silver; 75 ton smelter in contemplation; property owned in Philadelphia; Superintendent, Harry C. Kessler.

Original, silver copper; shaft 400 feet deep; pay stock from 3 to 8 feet wide; 27 consecutive monthly dividends paid to date of \$3,000 each; total, \$81,000; President, W. A. Clarke.

Gagnon, silver copper; shaft 500 feet deep; immense body of low grade ore in sight, also 5 feet of \$75 ore carrying 10 per cent copper; product, 40 tons per diem; total product to date over \$1,500,000 during six years; Superintendent and owner, J. C. C. Thornton.

Corra, silver copper; shaft 200 feet deep; drifts show 8 feet of ore assaying 40 ounces in silver, and from 8 to 12 per cent copper; owners, Roundbush & Young.

Poser, silver; shaft 100 feet deep; drifts, east and west show ore breast 18 feet wide, every pound of which pays to mill; its full width is being extracted; average value 30 ounces per ton; owner, W. A. Barnard, a leading quartz operator.

Mountain View, copper; shaft 400 feet deep; ledge supposed to be an extension of the Anaconda, and like the latter, is over 50 feet wide. Important results expected from present development. Owner, C. X. Larabee.

The above are the principal mines now being developed in the Butte district. They are all in active and successful operation. Many other good properties are idle, and some poor ones. It is a fact, however, that all those mines which have given any promise in the surface development have fulfilled the promise on exploration, and it may be safely stated that there has been less money wasted and lost in mining operations in Butte than in any other camp in the world. Butte has never yet received a black eye from a great mining fiasco, and from the present extraordinary productiveness of its mines and their indications of permanence, it is not likely that it ever will. Mining is pursued there on a safe business basis, and chiefly by close corporations and private individuals. The mines are worked in Butte, not in the New York and San Francisco stock exchange. They are exceptional for their extent, regularity and productiveness. Butte is, however, a big company camp. The mines are worked on an extensive scale, principally by powerful hoisting machinery and three compartment vertical shafts. Incline shafts, which frequently indicate the uncertainty and irregularity of the veins and the fear that they may disappear in some uncertain direction, are unknown in Butte. The veins all have a regular and uniform dip. The country is not in the least precipitous or broken up, and a "fault" has never yet been discovered in the district. With a single horse and buggy a man can visit any mine in the district in the space of half an hour. Butte is the county seat of Silver Bow county, which has an assessed property valuation of \$6,000,000 and a low rate of taxation.

Mining in 1883.

(CONTINUED FROM PAGE 44.)

The population of Montana, of which Helena is the political and commercial center, is about 15,000. Since the time mines were first discovered there it has produced about \$180,000,000 in precious metals, chiefly gold. Placer as well as quartz gold mining is still pursued in many parts of the Territory. The total product last year was supposed to be by residents considerably larger than the mint director credited to the Territory.

The Alice Mill.

One with 20 and one with 60 stamps, has made a good year's work. The following shipments of bullion were made during the past year:

January	\$90,040.57
February	73,564.07
March	77,303.13
April	76,439.14
May	70,309.91
June	67,975.53
July	87,342.22
August	119,109.56
September	120,436.83
October	110,030.70
November	107,670.80
December (estimated)	120,480.55

Total.....\$1,277,000.00

The ore comes mainly from the Magna Charta, but recent explorations in the Alice have resulted in largely increasing the output of that property, and it now produces about one-third of the ore the company is treating.

The Lexington mine produced last year \$1,300,000 in bullion. The Silver Bow mill turned out \$25,000 to \$30,000 a month last year. The Colorado smelter is supposed to have turned out \$1,000,000 in silver-copper matte in 1883. The Anaconda coppermine has shipped about 1,800 tons of ore a month to Europe for reduction. The Salt Lake *Tribune* says that the number of stamps running are Alice, 80; New Lexington, 60; Old Lexington, 10; Moulton, 40; Silver Bow, 30, and Dexter, 15; making the total 236, on dry ores; Clipper 5, and Burlington 8, on wet ores; making a grand total of 249. In smelters there are the Montana Copper Company, 8 roasting and one blast furnace; Parrot, 5 reverberatory and 6 calciners; Colorado & Montana Co., 5 furnaces and 2 buildings, and Bell Co., 2 blast furnaces. The Lexington Company employ 142 men, the Alice, 275; Parrot, 100; Moulton, 60; Montana Co., 100; Colorado & Montana, 100; Silver Bow Co., 75, and W. A. Clark, on various mines, 100 men.

The Butte *Inter-Mountain* says that "the shipments of copper matte and ore from the district of Butte last year will approximate 70,000,000 pounds. There is no camp in the world that can make an equal showing. Leaving Leadville out of the calculation, there are no half dozen camps in the United States whose aggregate outgoing tonnage equals that of this district. The copper journals of the East magnanimously credited Butte with an estimated output this year of 18,000,000 pounds of copper." The Montana people surely have good cause for rejoicing over their results the last year. Among other things, Montana has developed a mild diamond excitement, some diamonds having been found near Helena.

COLORADO.

Colorado still stands in the foremost position among the bullion producing States and Territories, its product ranking all the others. The State has had the advantage of late years of more capital than other regions, and a large number of producing mines have been developed. It lies furthest from us on this coast, so the details of operations in its mines are not of so much interest to us as the general results achieved. In the table given in the first part of the article is given the bullion product, and the following tables of the output we take from the Denver *Tribune*, as giving in a condensed form the results of the year's work:

The mining products of Colorado for the year 1883—gold, silver, copper and lead were as follows:

County.	Amount.
Boulder.....	\$ 400,000.
Chaffee.....	300,000.
Custer.....	800,720.
Clear Creek.....	2,000,000.
Dolores.....	200,000.
Eagle.....	930,000.
Fremont.....	20,000.
Gilpin.....	2,208,980.
Grand.....	10,000.
Gunnison.....	650,000.
Hinsdale.....	300,000.
Lake.....	18,691,208.
La Plata.....	128,000.
Ouray.....	700,616.
Park.....	400,000.
Pitkin.....	125,000.
Rio Grande.....	182,000.
Routt.....	75,000.
Saguache.....	100,001.
San Miguel.....	225,000.
San Juan.....	418,955.
Summit.....	350,000.

Total.....\$36,306,131

Product of the Grant Smelting Works for 1883, was:

Counties & Territories.	Total lbs.	Total ozs.	Total ozs.
Lake.....	28,775,050	2,048,907	3,291.38

Idaho Territory.....	134,160	16,158

Total.....40,290,300 3,464,505 38,247.24

The above product, figured on the basis of lead at \$90 per ton, silver at \$1.10 per ounce and gold at \$20.68 per ounce, makes a total output of \$6,397,308, distributed as follows: Lead, \$1,813,065; silver, \$3,819,550; gold, \$764,693.

Shipments of the Boston & Colorado Smelting Company for the year 1883, were as follows:

LOCALITY.	GOLD.	SILVER.	COPPER.	TOTAL.
Gilpin Co.....	\$463,000	\$83,000	\$87,000	\$606,000
Clear Creek Co.....	44,000	640,000	41,000	725,000
Boulder Co.....	146,000	50,000	206,000
Lake Co.....	56,000	56,000
Summit Co.....	152,000	152,000
Park Co.....	6,000	80,000	86,000
Gunnison Co.....	3,000	13,000	16,000
Utah Co.....	9,000	7,000	16,000
Hinsdale Co.....	4,000	31,000	12,000	47,000
Saguache Co.....	11,000	11,000
San Juan Co.....	2,900	16,000	6,000	24,000
Ouray Co.....	15,000	3,000	18,000
Chaffee Co.....	11,000	11,000
New Mexico.....	12,000	101,000	10,000	123,000
Arizona Co.....	13,000	4,000	17,000
California.....	4,000	88,000	40,000	132,000
Montano Co.....	63,000	646,000	130,000	839,000
Miscellaneous.....	240,000	417,000	28,000	685,000

Totals.....\$909,000 \$2,576,000 \$362,000 \$3,007,000

This includes purchases from smelting companies, sampling works and ore buyers, and it is impossible to tell what district it came from.

The following is the statement of the Miners' Smelting Works at Golden, for the year 1883:

LOCALITY.	TONS.	GOLD.	SILVER.	COPPER.	TOTALS.
Clear Creek.....	2,900	\$ 8,355	\$158,735	\$ 4,265	\$171,355
Gilpin.....	2,950	88,000	16,740	11,718	117,183

Mint Report.

The statement of the United States Mint at Denver, showing the business of 1883 and a comparison with that of 1882, is as follows:

	1882.	1883.
Number of deposits.....	747	2,010
Net value of deposits.....	\$501,329.64	\$1,370,166.30
Value of bars manufactured.....	504,790.03	1,371,634.61
Value of gold bullion sent to mint at Philadelphia for coinage.....	450,306.52	1,359,089.80
Value of gold bars refined and returned to depositors.....	24,428.51	12,595.01

ARIZONA.

If local authorities are to be credited, Arizona, in the matter of bullion production, has more than held her own the past year. According to the returns of Mr. Valentine, there has, however, been some falling off in the year's bullion output for this Territory, the decline, as compared with the preceding year, amounting to something over \$1,000,000. However this may be, there has, no doubt, much progress been made in the mining industry of the country, this shrinkage being due to a diminished production on the part of a few large companies, and not extending to the mines generally.

Besides the disadvantages of a hot and arid climate, a scarcity of timber, and a rather poor soil, Arizona has, first and last, suffered from a variety of extrinsic troubles, some of them of a serious kind. The hostility of the murderous Apache has, from the first, done much to discourage immigration, and otherwise retard the progress of the Territory. Before these savages were well out of the way the Texas Cowboys began to arrive in undesirable numbers. Following this disturbing element an army of tramps was left in the country on the completion of the railroads, this last addition swelling the turbulent and lawless population to an inconvenient and even dangerous degree. But as the regular army, assisted by the citizen soldiery, have succeeded in subjugating the Apaches, so have the public authorities, aided by the people, shown themselves able to cope with these unruly characters, the most of whom will be forced to betake themselves to honest labor or make an early exit from the Territory. Relieved from the presence of these unwelcome classes, Arizona will be likely to advance hereafter even more rapidly than she has done, her progress thus far denoting the extent of her mineral wealth, while it reflects creditably on the courage, perseverance and enterprise of her people.

The bullion product of this Territory amounts to about \$50,000,000, all told. Adopting the figures of Mr. Valentine, the product for 1883 amounted to \$8,183,743, as against \$9,298,276 in 1882. As a producer of copper, Arizona ranks 2, of silver, 4, and of gold, 10 among the States and Territories of the Union.

The Tucson *Star* has compiled with much care data concerning the mines of the Territory and their output for 1883. They place the bullion product one-third higher than Mr. Valentine's estimate, but we give the figures as follows:

COPPER CROP.	AMOUNT.
Arizona Copper Co., Clifton, lbs.....	8,106,575
Detroit Copper Co., Clifton.....	4,035,525
Copper Queen, Bisbee.....	7,950,000
Old Dominion, Globe.....	4,590,000
United Verde, Yavapai county.....	1,763,153
Omega, Pima county.....	350,000
Columbia, Pima county.....	273,000
Long Island, Globe, estimated.....	475,000
Tacoma, Globe, estimated.....	400,000
Buffalo, Globe, estimated.....	250,000
Cochise Copper Co., no report.....

Total, lbs.....28,108,253

There has been a large amount of copper ore shipped out of the Territory of which we give no estimate; also scattering shipments of copper bullion. This includes the Cochise Copper Company, which has been running two furnaces part of the year. All told, it will probably reach 1,000,000 pounds, making the total aggregate nearly 30,000,000 pounds. The *Star* estimates the product of 1884 at not less than 50,000,000 pounds.

SILVER AND GOLD.

Estimated output not reported.....	1,500,000
Value of copper bullion.....	4,228,987

Grand total.....\$12,322,336

Since the advent of the railroad the natural resources of the Territory have been greatly developed. The Narrow Gauge railroad from Tucson to Globe is now under course of construction, which, when completed, will open up one of the most wonderful mineral fields in the Southwest. It will tap the coal-fields of Deer Creek, the timber lands of the Pinal range, and be the means of furnishing cheap and quick transportation for fuel, ore and merchandise, which will put into operation hundreds of mines of copper, silver and gold which are now idle for want of cheap fuel. The A.

M. B. road from Globe to the A. & P. is now looked upon as a fixed fact, and its construction will go forward during the year. Also the road from Prescott to the A. & P., which will in all probability be under way in a short time.

Oro Blanco District.

EDITORS PRESS:—Oro Blanco is in the southwestern part of Arizona, and forms the boundary of Sonora, Mexico. The latest strike and the richest ore in this neighborhood was in the Franco-American, owned by Gen. G. W. Deitzler, of San Francisco. At 50 feet he drifted seven feet through solid ore and struck white quartz. He is now drifting in an opposite direction and is still in good pay ore, averaging 33 per cent. copper and \$200 per ton in silver, and apparently an inexhaustible mine. The Warsaw Mill shut down a few days ago for want of water. The last run was a very profitable one, particularly on ore from the Cross lode and the Montana mine. Esperanza Mill, Mr. Blaisdell superintendent, would have started up before this, it is supposed, had they not lost their drill-bit in the well while boring for artesian water. He is now putting up a steam power and laying pipe to the Calaveras mining shaft, where he expects to find an abundant supply of water. Messrs. Clarke and Dixon have a fine body of ore in their mine at the Sierra Colorado. It carries from \$600 to \$900 per ton, gold and silver. I could mention other fine prospects, but, for the present, adios.

Oro Blanco, Jan. 3. HAMPTON WEED.

Development in Mojave Country.

EDITORS PRESS:—I send herewith a statement of the progress of mining development in this district and county as requested in the last issue of the MINING AND SCIENTIFIC PRESS. I give a simple statement of the facts in regard to the progress of mining here, without any exaggeration.

Since the advent of the A. & P. R. R. at Kingman, the nearest station to the mining camps of Walapai district, mining has received an impetus which it never knew before. Formerly only ores of a very high grade could be worked or shipped with profit. Now, however, low grade ores are almost as valuable as high grade ores were formerly. Fifty ounces of ore is now worth as much as 100 ounces of ore was two years ago. Miners are steadily beginning to realize this fact, and now almost every miner in Walapai district is taking out ore for shipment, either to San Francisco, Benson or Colorado. The first car load of ore shipped by a miner after the railroad reached Kingman was taken out at Chloride and went to the smelting works at Albuquerque. The very satisfactory results obtained from the working of this car load induced others to ship to the same smelter. It was immediately followed by three car loads of ore from Stockton, one from Cerbat, two from Chloride and one from Todd Basin, all of which, owing to the failure of the Albuquerque smelter, were forwarded to Pueblo, Colo.

The demand for lead ores in the San Francisco market stimulated the extraction and shipment to that market of lead ores of which there is an unlimited reserve in Walapai and district. The New London mine, at Cerbat, has shipped three cars of lead ore within the past three months, and is now producing twenty-four ounce galena at the rate of three or four tons per day, the result of three men's labor. The Champion mine, at Cerbat, has shipped six cars of galena ore carrying from 23 to 27 ounces silver, and from 50 to 64 per cent lead, and is at present producing four tons daily, working seven men.

Salisbury & Co., of the Benson Smelting Works, having purchased the Schuykill mine at Chloride, are now working eleven men and extracting six tons of heavy lead ore daily. The galena shows for over 2,000 feet along this ledge, on the Schuykill and adjoining claim, and is from 6 inches to 3 feet in width, carrying from 17 to 24 ounces silver per ton. The ore from the Schuykill is being shipped to Benson, Arizona. The adjoining claim is being worked on a very small scale by one man, and produces about two tons daily. There are several other mines in the vicinity of Chloride which are capable of producing from one to five tons of galena per day to the man, but owing to lack of enterprise are not being worked at all, or else working on a very small scale. There are many other claims near this camp which are producing high-grade ores—from \$80 to \$350 per ton. At present the shipment of ores from Chloride is larger than from any other camp in the district, and the outlook promises a steady increase in prosperity. The company work is being steadily pushed on the Cupel at Stockton, but with little success so far. (Since writing the above an 8-inch streak of ruby silver ore has been struck in the Cupel, assaying \$300,000 per ton.)

In doing the assessment on the Lone Star, near Mineral Park, in December, about three tons of \$350 ore were extracted on the 100-foot level. This mine had been shut down for nearly two years, but has now started up again with prospects for a steady run.

The American Flag mine, in Maynard district, is shipping some high-grade ore. The ore from this mine, together with all batches of ore less than a carload from Walapai and Maynard districts, is bought by the Arizona Sampling Works, at Kingman, and shipped to the Argo Smelting Works. Work is now being prosecuted in the crosscut, which is paying well.

The Hackberry mine is working a good force than usual, and preparations are being

Mining in 1883.

(CONTINUED FROM PAGE 48.)

made to erect a forty-ton water-jacket at that place. Upon the whole the mining outlook in the Mohave is better than ever before, and while there is no excitement, there is what is still better, a gradual but steady increase in mining enterprises, with every indication that every advancement made will be permanent. From the most accurate information I can secure, the Arizona Sampling Works have shipped about 500 tons of ore to Colorado.

HENRY P. EWING.

Mineral Park, A. T., Jan. 2, 1884.

The *Republican* concludes its review of Tombstone district by recapitulating the amounts of ore and silver produced by the various mines of the district. Most of the figures given below are authentic, derived from the books of the company. The production of the Grand Central and Contention mines for the last five months we had to estimate. In this, as in all other cases where we were compelled to estimate the production, we have taken the lowest figure, so as to be sure and not overestimate the production. Also, many small lots of ore have escaped our notice, the shipments of them never having been recorded. On account of these reasons, the actual production far exceeds this estimate:

CONTENTION.	Tons.	Value.
First five months in 1883.....	13,652	\$553,085 95
July and August.....	2,455	\$4,869 64
Last five months.....	19,060	\$50,000 00
Total.....	35,167	\$987,955 59

	\$3,926

Total value.....	Value.
	\$1,136,369 27
Dividends during 1883.....	\$500,000 00

Of Yavapai county, the Prescott *Courier* makes the following estimate:

United Verde.....	\$900,000
Howell Co.....	400,000
Black Warrior.....	100,000
Silver Belt.....	200,000
Tiptop & neighboring mines.....	75,000
Dosoris.....	250,000
Pine Spring & sister mines.....	75,000
Blue Dick.....	20,000
Bigelow's.....	5,000
Tuscania.....	20,000
Groom Creek.....	10,000
Other mines.....	10,000
Total.....	\$1,385,000

The foregoing estimate takes in the value of bullion product at home, of placer gold and of lots of rich ores which were shipped to Pueblo, Colorado and Benson, Arizona, for treatment.

We give these figures and estimates with their source without pretending to vouch for their accuracy, but it is impossible to get exact data on the subject.

The purchase of the Quijotoa mines by the well known bonanza firm of this city has caused considerable excitement in Arizona. Four companies have been formed—the Peer, Peerless, Combination and Weldon—each with a capital stock of \$10,000,000. Comstock miners have been sent down to take charge of the mines. There has been a great rush to the district, and other mines are reported found in the neighborhood.

The *Star* says further: The bonanzas have not yet been all discovered in Arizona. When the Silver King was first opened, it was said "nature had put the whole mineral business of Arizona in that spot." When the Clifton copper mines were discovered, it was believed they were the only copper mines in Arizona worth developing. But in silver we shortly discovered Tombstone, which has turned out its millions. In copper we have our Bisbee, the Globe country, and other sections that are producing millions of pounds annually, and still new discoveries are being made of the bronze metal. Now comes the discovery of the Quijotoa, and the rush to that camp is all the rage. No doubt but it will yield its millions. But there are still other Silver Kings, other

Tombstones and other Quijotoas in Arizona undiscovered. The prospecting business of the Territory has but fairly begun. The production of the bullion is just commencing.

Tombstone is yet the principal bullion-producing camp, and the year just passed has been replete with much importance to that camp and surrounding district. The *Republican* of that place says:

No one can deny that to-day there are many more mining claims in course of development than ever before, while as a place of business and an important mining center for the many surrounding districts, as well as the daily increasing demands of Northern Sonora, make this the mining headquarters of the Territory. For the information of distant readers it may be stated that the mining district of Tombstone is daily enlarging its boundaries, and we are within the mark when it is stated that the known deposits of ore extend from the town to within a couple of miles of Charleston in a direct northerly and southerly direction about eight miles and whose breadth varies from two to four miles. Hardly a week passes but some new find or discovery is made, and we now chronicle one that is second to none in importance. The increasing extent of copper deposits found both in this, the southeasterly part of Arizona, as well as in the northerly part of Sonora, especially in the Canansa and Manzanil mountains, is worthy of record, as when these districts are thoroughly explored they will be able, without doubt, to hold their head up with the lake Superior regions.

NEW MEXICO.

This Territory is the oldest mining section of the country, but even in the old days of Spanish possession the Indians drove away the miners. It is only of late the country has been safe for prospectors. The advent of the railroads has changed matters so that themines are now being opened. The principal discoveries have been in the southern part of the Territory—in the Black range and thereabouts. In the northern and central counties many rich and extensive deposits exist, but mining is retarded by the existence of land grants. The Mint Director figures up the production of 1882 as follows:

Bernalillo County.....	\$5,000
Colfax.....	20,000
Dona Ana.....	920,000
Grant.....	460,000
Lincoln.....	55,000
Santa Fe.....	40,000
Socorro.....	440,000
Total.....	\$1,950,000

Of this only \$150,000 was gold, the balance being silver. No estimate of production by county is at hand for 1883, but Wells, Fargo & Co., put the total figures for 1883 at \$3,413,519, of which only \$173,000 was gold; of ores and base bullion they count up \$2,048,000. No doubt that the mines will continue to increase their products from this on.

It cannot be said that New Mexico has made a brilliant record the past year, notwithstanding the reported richness of many of her mines. They do not seem to have come down to a good business basis as yet, and there is too much of the "boom" and speculative fever for the good of the mines themselves. The evil results are apparent in a sort of distrust of the New Mexican mines. Some very good claims will have to make good records of bullion production to again inspire the confidence in the regions, without which its mining industry will not flourish. In the past there have been serious obstacles to the introduction of sufficient capital. Until the railroads were built the Territory was practically inaccessible. There were but few inducements for prospectors, and less for miners or mining companies, because they had to be exceptionally rich mines to bear the cost of working and the transportation of supplies and products. The opening of the railways changed this. Prospectors came in; they located the country and made known to some extent its vast resources in the various minerals. But, unfortunately, another class came—mine operators, mining sharks, professional schemers—ready to trade upon the popular curiosity, to take advantage of the popular ignorance.

OREGON.

Viewed in the light of developments made, only in a limited sense can Oregon be considered a mining country, her standing in this respect among the States and Territories of the Union being as follows: Gold 7, silver 9, coal 17, iron and steel 27. But, while so comparatively little has been done in the way of turning this class of her resources to practical account, Oregon is by no means deficient in mineral wealth, the great agricultural and grazing advantages of the State having tempted labor and capital to embark in farming and stock raising, to the neglect of mining pursuits. The remote situation of the mines here, the principal districts being far inland and difficult to reach, has further tended to check mining operations in this State. The principal mineral resources of Oregon, so far as ascertained, consist of gold, silver, iron, coal, copper, lead, nickel, antimony, etc. Of these only the four first named have as yet been much utilized. Salt, soda and cinnabar are among the mineral products of the State—deposits of the latter,

found in Douglas county, having lately been worked in a small way.

The total bullion product of Oregon, including that of 1883—\$600,000—amounts to about \$62,000,000. Of this, some \$40,000, taken out during the past six years, consists of silver. The smallness of the product of 1883 was owing to lack of water for working the hydraulic mines and gulches, from which more than two-thirds of the Oregon gold is obtained. The auriferous deposits of Oregon occur in much the same manner as those of California, and are worked by all the various methods and appliances in use in this State. The number of men engaged in gold mining in Oregon amounts to about 4,000, of whom more than one-half are Chinese.

It has always been more or less difficult to obtain reliable information as to the amount of gold and silver annually produced in Oregon, because so much of the mining is done by Chinese, who are reticent as to their operations, and much of the dust is carried away by private individuals and no record kept. The production of 1882 was less than 1881, if we can take as a basis the fact that the gold reported as received at the mint was \$140,000 less than the previous year. That left the product for 1882 as \$865,000, divided as follows: Baker county, \$195,000; Benton county, \$5,000; Coos county, \$5,000; Curry county, \$20,200; Grant county, \$265,000; Jackson county, \$137,000; Josephine county, \$177,000; Union county, \$60,800. Last year, as stated above, the yield was still less. In Baker county placer mining has been one of the principal industries for the past twenty years, and still gives employment to a large percentage of the population. It is, however, being gradually turned over to Chinese, who pay good prices for ground already worked over by white men, as they live so cheaply and are satisfied with small returns. Baker city is about the center of the mining section, nearly all the mines of the county being within a radius of forty miles of that place.

Grant county is in eastern Oregon. The old mines found on Canon, Dixie, Elk and Granite creeks as far back as 1862 are yet worked, but principally by Chinese, who are working claims abandoned by white men. The principal quartz mines are in the northern part of the county, on the range of mountains between the middle and north forks of the John Day river, including Elk and Granite creek districts. The quartz mines are worked and owned by white men.

As a general rule, the quartz milled in Oregon is of a higher grade than that worked in California, the mass of it yielding from fifteen to twenty dollars per ton. But it costs more to work it here, by reason of the long wagon transportation required to get machinery and supplies into the mines, the most of which are located far distant from both railroad and water communication.

There are now about thirty quartz mills in this State, besides a few arrastras. The former carry an average eight stamp each, and are nearly all run by steam power. As none of these mills have been provided with means for concentrating and working the sulphureted ores, a good deal of gold is lost. Millmen have as yet aimed to save only free gold.

Quartz Mining.

While there is something being done in this line of business in nearly all the mining counties of Oregon, the most extensive operations are being carried on in Union, Grant and Baker counties, in the northeastern part of the State. The more active quartz centers here consist of the Eagle creek, Elk, Olive, Granite creek, Baker city, Burnt river, Union and Rye valley districts; all of which contain numerous gold bearing lodes of good promise, many of which have been partially and some very thoroughly opened up. In the Ochoco district, Wasco county, several companies have been operating in quartz during the past year, with encouraging prospects, making, according to report, a good showing of both gold and silver.

While most of the auriferous ores of Oregon carry the gold in a free state, some of them are vitiated by the presence of antimony and other base substances that prevent the gold amalgamating with mercury. In many instances the gold is alloyed with a small percentage of silver, some of it carrying quite a large amount of that metal. The bullion turned out by the mills in the Rye valley district is worth only about \$12 per ounce; that made in some localities being worth not over five or six dollars per ounce, owing to the presence of so much silver. Occasionally the gold dust obtained from the placers is found alloyed in like manner, being worth only \$9 or \$10 per ounce.

Hydraulic Mining.

As with the quartz, so are the heavier hydraulic operations in Oregon confined to the northeastern group of mining counties, the gravel deposits in the southwestern and western portions of the State being generally shallow, while water there in large supply is not easily obtained. In the northeastern counties the gravel deposits range from 20 to 60 feet in depth. The most of them are free alike from superincumbent and imbedded barren matter, the mass of the material paying throughout. While these deposits have thin blue gravel and rich channels, the Pliocene or "Dead Rivers" proper, such as are found in California, do not occur here, yet, paying so uniformly, being free from sterile layers of pipe clay and sand, and capable of being washed with comparatively

little water, these gravel banks can always be worked with more or less profit.

For introducing water into these hydraulic and other diggings a large number of ditches have been constructed. The most of these works are, however, short and of limited capacity, ranging from three to five or six miles in length, and carrying from two hundred to five hundred inches of water each. There are perhaps thirty ditches in the State, ranging from ten to sixty miles in length, and in carrying capacity from 500 to 2,500 miner's inches each. These ditches depend for the most part on the melting of the snow on the mountains, where they head, for their supply of water. Not being very lofty, the snowfall on these mountains is comparatively light, and melting early in the summer leaves the ditches dry, or nearly so. This makes a short water, and consequently a short working season for the hydraulic miner, its average length being hardly more than three months. Hence his enforced idleness for the most of the year, and a greatly restricted production of bullion.

WASHINGTON TERRITORY.

While there are some promising deposits of the precious metals in this Territory, its principal mineral wealth consists of iron and coal, both of which are found here in great abundance and of good quality. Both gold and silver-bearing lodes have been met with in different parts of the Territory. Very little work has, however, been done upon them, and whether or not they are sufficiently rich to warrant a further expenditure of money upon them, remains to be seen. The placers of Washington have from time to time attracted some notice, but none yet discovered have amounted to much. There was a great excitement a few years since about gold mines on the upper waters of the Skagit river, and a good many men suffered much hardship forcing their way to these diggings during the winter, as numbers are now doing into the Cœur d'Alene country, only to meet with sore disappointment in the end, the mines turning out to be poor and of limited extent. All the gold obtained from this Skagit country has amounted to only a few thousand dollars per year, the small number of men who have since worked the mines there having barely made day wages for a portion of the year, it being impossible to continue operations there during the winter. The total bullion product of Washington Territory, nearly all gold, amounts to scarcely more than a million dollars. Jno. J. Valentine, in his statement of the precious metals produced on this coast, credits it with a production of \$63,526 for the year 1883, of which \$351 was silver.

The principal coal fields of this Territory extend at intervals along the easterly side of Puget sound for a distance of more than a hundred miles, the three chief points of shipment being Seattle, New Tacoma and Bellingham Bay, shipments from the latter having been small for a number of years past. During the thirty years that coal mining has been carried on here over two and a half million tons of coal have been exported from the country, the most of it during the past few years. The Newcastle mines, which ship from Seattle, are the largest producers. The quantity of coal sent from that place since 1871, when the mines tributary thereto were first opened, amounts to 1,200,000 tons. The product of the Wilkeson and the Carbonado mines, already large and rapidly increasing, seeks outlet through New Tacoma, where coal bunkers of immense capacity have been erected. While the coal industry of this Territory is so undergoing enlargement every year, renewed attention is likely to be paid to the manufacture of iron there, as the large demand for this metal will, it is expected, lead to a resumption of operations at the works erected near Port Townsend several years ago, but which of late have been idle. At the end of this review, under the subject of coal, the product of the mines is given.

ALASKA.

We find the gold-seeker here engaged in the irrepressible conflict, battling manfully, as he always does. But, here in Alaska, under many disadvantages yet with encouraging prospects, only on Douglas Island and on the mainland opposite in the vicinity of Harrisburg, have quartz lodes of much promise yet been discovered; and this, probably, because very little prospecting has elsewhere been done. The principal quartz vein on Douglas island is represented to have an average width of 125 feet—all pay ore, that will mill \$8 per ton, free gold. A five stamp mill put up near the lode has been running quite steadily during the past year. Another five stamp mill, erected on a quartz vein near Harrisburg, though completed has not yet commenced running. The ore here is also of good grade, and as there is plenty of it this enterprise will be likely to prove a success. Several arrastras have been running on it for some time past with excellent results. From all accounts there is enough ore in these two localities to give long continued and profitable employment to a large number of stamps.

The quartz lode on Douglas island being much decomposed on the surface has been

(CONTINUED ON PAGE 50.)

JOSEPH MOORE, Superintendent.

THE RISDON IRON AND LOCOMOTIVE WORKS,

S. E. Corner Beale and Howard Streets, San Francisco, Cal.,

MANUFACTURERS OF.....

STEAM SHIPS, MARINE ENGINES,
MARINE BOILERS, SCREW PROPELLERS,
CENTRIFUGAL PUMPS, STEAMSHIP PUMPS,
STEAM STEERING GEAR, STEAM WINDLASSES,
STEAM CAPSTANS, CARGO WINCHES,
LAND BOILERS, SHEET IRON PIPE,
IRRIGATING PUMPS,

HYDRAULIC MACHINERY, PUMPING MACHINERY,
COMPOUND ENGINES, CORLISS ENGINES,
POPPET VALVE ENGINES, SIDE VALVE ENGINES,
HOISTING ENGINES, AIR COMPRESSORS,
SUGAR MACHINERY, QUARTZ MILLS,
ROASTING FURNACES, IRON TANKS,
ROPE POWER TRANSMISSION.

Prompt Attention Given to All Kinds of Repair Work.

ALSO HAVE SPECIAL FACILITIES FOR THE MANUFACTURE OF ALL KINDS OF

SHEET IRON AND PLATE IRON PIPE,

Having Made Most of the Principal Pipe Lines on the Pacific Coast.

AMONG THE WATER COMPANIES NOW USING THEIR PIPE ARE:

Spring Valley Water Works, San Francisco, over 20 miles, varying in diameter from 22 inches to 30 inches.

The Cherokee Flat Mining Company, over 12,000 feet of 30-inch pipe, a portion of which sustains a pressure of 380 pounds per square inch.

The Virginia and Gold Hill Water Company's pipe line, a portion of which sustains a pressure of 750 pounds per square inch.

Portland Water Company, Portland, Oregon, several miles of 30-inch pipe.

The Hawaiian Commercial Company, several miles of 30-inch pipe on the Island of Maui.

Also several miles lately constructed for Messrs. W. S. Hobart and A. Hayward for the Plymouth Consolidated Mining Company, and numerous other places where smaller quantities are in use.

PRICES FURNISHED ON APPLICATION.

VICORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED!

ALL POWDERS manufactured by the California Vigorit Powder Company are SUBMITTED, during the course of manufacture, TO SCIENTIFIC and accurate TESTS for safety and strength. They are Tested for Safety against Friction, Fire, a Temperature of 212 degrees Fahr., and the various shocks to which Powder is Liable in Practical Handling.

The following qualities are common to all grades of Powder manufactured by the Company:

SAFETY, NON-LEAKAGE, FREEDOM FROM NOXIOUS GASES, UNIFORMITY AND STRENGTH.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will be GIVEN IN FOOT POUNDS. Send for Pamphlet showing methods of testing the different qualities of all powders. The Company manufactures

DETONITE.

This is an explosive involving new principles and recently patented. It is the Strongest Powder ever placed on the Market, in this country or abroad. It is the Safest Strong Powder ever made. For very refractory rock this Powder is the most economical in the market.

VIGORIT, No. 1, XX.

This Powder is Stronger than the Highest Grades of Hercules or Giant. It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any corresponding grade in the market.

LOW POWDER.—Vigorit, L. P.

This is a Powder suitable for Bank Blasting, Log Splitting, or the work generally in which Black Powder can be used. It is Stronger than Black Powder, having from twice to ten times the effective strength, depending on resistance. It is Superior to Judson Powder, in being more sensitive to the cap and more convenient in handling.

Best qualities SINGLE, DOUBLE and TRIPLE TAPE FUSE; also agents for X, XX, XXX, XXXX, and XXXXX BLASTING CAPS, at Lowest Prices in the market, and quality guaranteed.

Mining in 1883.

(CONTINUED FROM PAGE 48.)

worked for several years past by placer methods. Some diggings, in a sort of basin, three miles above Harrisburg have also been worked by hydraulic washing and paid well.

Elsewhere in Alaska no largely paying placers have yet been discovered, though some gold has been met with on the bars along the Yukon river for a distance of several hundred miles, and it is thought that with more extended and careful prospecting paying bars will be found along that stream. The chances are that it will be more thoroughly explored the coming summer than ever before.

A long way to the northwest on Fish river, a heavy body of argentiferous galena was discovered two or three years since by parties resident of Oakland, who at once took measures for getting out the ore and shipping it to this city. The wrecking unfortunately of a schooner loaded with supplies in Golovin bay, near the mouth of Fish river, has prevented the company getting much of this ore to market. Next year they expect to send down a good deal of it, as it can be easily mined and they have a steamer for bringing it down to the mouth of the river, which can be approached by large vessels. The vein at this place is reported to be 40 feet thick, composed mainly of ore carrying \$150 in silver and \$10 gold, to the ton, with 60 per cent lead.

The hullion production of Alaska is officially given at \$15,000 for 1881, and \$150,000 for 1882, the product for 1883 having been about the same, or probably a little more than that of 1882. The present year will, it is thought, bring some increase.

Beds of superior coal, by some pronounced anthracite, exist on Admiralty island, close to deep water. Along Copper river deposits of rich cupriferos ore have been found; also considerable masses of metallic copper. Beds of marble equal to the best Italian stand so close to the deep inlets that the stone can, by means of gangways of no great length, be placed on shipboard, these beds being so extensive that blocks of any desired size can easily be broken out.

Except the few discoveries made immediately on the coast hardly anything is known as yet in regard to the mineral resources of Alaska, the heavy timber and the mountainous character of the country, coupled with the deep snows in winter and the frequent heavy rains at other seasons of the year, having prevented, as they always will greatly interfere with explorations being carried on in the interior. That the mineral wealth of the country will ultimately prove to be considerable may be inferred from what the limited researches already made have brought to light, this being apart from its fur trade, fisheries, lumber, and possibly other resources of large commercial value. What of mineral riches may be contained in the gloomy realm that stretches away to the Arctic ocean is yet to be ascertained. The fact of some gold having been found along one of the great rivers that traverses this region will be sure to carry the veteran prospector into it at an early day, the hope of striking placer diggings operating on the imaginations of this class of men after the manner of the electrical current, the nearer the North Pole the stronger the attraction, and if that mythical pivot is ever reached it will be not first by Arctic explorers, but by the California gold hunter.

BRITISH COLUMBIA.

While the population and general business of this Province have been much increased during the past year, there has been no increment of bullion, nor are any important mineral discoveries announced for the year. Even the usual output of coal, the most staple mineral product of the country, has, by reason of labor troubles, been somewhat diminished. The total bullion yield of British Columbia, consisting wholly of gold, amounts to about \$20,000,000, the product of 1883—some \$700,000—being included in this sum. Although the value of the gold taken out here has been steadily declining for nearly ten years past, it is probable that the production of this metal will undergo some increment hereafter, the output of coal being quite sure to do so. The Province is beginning to feel the vivifying effects of the Canada Pacific railroad approaching it from the east, and the western portion of which is now in course of rapid construction within its borders.

Besides the Cariboo district, whence most of the gold produced in British Columbia has been taken, there are other placer mines in the country, some of them probably quite extensive. Some little gold is still being gathered on the bars of Fraser river and its tributaries, and pay diggings are reported to have been lately found on Deloivre river, a branch of the Mackenzie, at a point about 250 miles from Dease lake. Bars that will pay small wages have also been found on Chum creek, and at several other places in the Province.

The placers of the Kootenay country, worked extensively many years ago, are far from being exhausted; it being the opinion of those best acquainted with this region that the diggings there have been merely skimmed of their surface gold; and that the more prominent deposits remain untouched. During the earlier stages of their history, these mines were worked under many disadvantages, the Indians being at times troublesome, and the cost of getting in supplies great. But all this has been or

is likely soon to be changed, the Northern Pacific railroad, already finished, passing within a hundred miles of this country, while the Canada Pacific, which will be completed within another two years or less, approaches it still nearer. Through the construction of a lateral railroad this Kootenay country could be connected with the Canada Pacific road, and thus be made tributary to the latter to its very great benefit. A plan for the construction of such lateral road, in connection with the navigation of some waters in that region, has been projected, and will very likely be carried out, as the interests of the Province and the Canada Pacific Company require that the trade of this district be secured to them instead of being diverted to the Northern Pacific road, as much of it otherwise might be. This Kootenay country, by reason of the large amount of good farming and grazing lands and the mineral wealth it contains, is by far the most valuable section of British Columbia, its proximity to two great overland thoroughfares, whereby its early settlement is assured, adding greatly to its prospective importance. Large veins of silver and copper bearing ores, many of them of high grade, are reported among recent discoveries in this section of country, also deposits of argentiferous galena of great magnitude, this ore, though low in silver, running high in lead. That this region is traversed by a rich and extensive mineral range admits of no doubt; its agricultural resources being also considerable. With improved means of access and cheapened transportation, it may well be supposed that modern enterprise, quickened by competition, will hasten the settlement of this country and lead to its many forms of natural wealth being turned to practical account.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'S SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

MACHINE FOR HOOPING BARRELS.—Thos. C. Duff and Roht. I. Allan, S. F. No. 291,583. Dated Jan. 8, 1884. This invention relates to a machine by which hoops may be forced upon barrels or casks; and it consists of a series of adjustable rollers attached to a driving mechanism by which they may be caused to travel around upon the edges of the hoop (the cask standing vertically beneath for the purpose), and, in combination therewith, of a means by which the rollers are carried downward as they revolve until the hoop has been forced on as far as necessary.

WATER COOLER.—Wm. A. Hawthorne, Hawthorne, Nev. No. 291,595. Date, Jan. 8, 1884. This water cooler consists of a double compartment water-chamber, one compartment provided with an inlet, the other with an outlet, a peculiar connection of wrapped pipe between the two compartments, an air space or jacket surrounding the two chambers and connecting pipe and communicating with the outside atmosphere, whereby a draft or circuit is formed, and a means for spraying or keeping wet the entire surface of the chambers and connecting pipe.

ANIMAL TRAP.—Geo. W. Jolly, Paraiso Springs, Monterey Co., assignor one-half to T. J. Hattabaugh, San Jose. No. 289,268. Dated Nov. 27, 1883. This is a spring trap to be placed in the holes of rodents. The advantage claimed for the trap is principally in the method of impalement against the upper part of the burrow which will thus effectually prevent escape.

LOGGING ENGINE.—John Dolbeer, S. F. No. 290,755. Dated Dec. 25, 1883. This is a novel apparatus for moving logs or other heavy weights; and it consists of a vertical gipsy or winding device with gearing, by which it is connected with the engine and a swiveling rope-guide. The bed and frame are portable.

DIRT-SCRAPER.—C. Endicott, Kingsburg, Fresno county, No. 291,585. Dated Jan. 8, 1884. This scraper is for leveling land, and it consists in the arrangement of the bowl, wheeled axle, and the means for connecting them, the draft, and the means for dumping the bowl.

MINERS' COMBINATION TOOL.—John Ryan, Salt Lake City, No. 291,627. Dated Jan. 8, 1884. This combination tool is a device for holding a candle, for cutting fuse, for pressing the caps thereon, and for sustaining the tool.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.
B. W. CROWELL—Nevada.
J. M. LEHY—San Bernardino and San Diego counties.
J. J. BARTELL—Sacramento county.
C. E. CURTIS—Kern and Fresno counties.
A. S. DENNIS—San Mateo and Santa Cruz counties.
A. C. KNOX—Colusa, Tehama and Yolo counties.
W. R. McQUIDDY—Tulare county.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to discontinue it, we shall positively demand payment for the time it is sent.

Eucalyptus and Boiler Scale.

Some time since mention was made in the newspapers of the country of the discovery of a successful boiler scale remover prepared from the leaves of the eucalyptus tree. Experiments had been made by Mr. Downie, of Salinas City, the discoverer, and Mr. McGillivray with whom he was associated, and it was claimed that the best results have been obtained. Since then the article had been put in the market by the Downie Boiler Incrustation Prevention Co., who now own the patents, and it has come into pretty general use on the Pacific coast. Twenty thousand dollars was raised for a working capital on the sale of rather a small part of the stock, and patents secured through Messrs Dewey & Co. for all the principal countries of the globe. The preparation must, upon the showing made by its use, have great merit in it. The principal difficulty with scale removers—at least, with those which would remove the scale—was that they tended to eat into the iron. It appears that the Downie Scale remover is made by boiling eucalyptus leaves in steam boilers made of regular boiler iron under 40 pounds pressure, and that the iron is now, after a constant use of eight months, as sound as when it came from the shop. All the engineers who have used it any length of time, as far as we can learn (such as those on the Pacific Coast Steamship Co.'s boats, the Baldwin and Palace Hotels, Union and Fulton foundries, Starr's Mills), testify that not only does the preparation not eat into the iron, but that it absolutely prevents rust; and that in the case of steamboats it prevents pitting from galvanic action. No new scale forms after the preparation is put in the boiler, and as soon as the old scale is removed the iron is covered with very thin coating which preserves the iron from rust or corrosion. Nearly a thousand boilers in San Francisco and the neighborhood are using the Downie remover, and the reports of the engineers are very unanimously in favor of its efficacy. There are many kinds of waters in this State, and in Nevada, and Utah, and in all kinds the results have been very satisfactory. Many virtues have been claimed for the eucalyptus tree, but it could confer no greater good on a very large part of humanity than by keeping the steam boilers clean, by decreasing the waste of fuel, labor of engineers and the danger of explosion. It seems indeed fortunate that our State has been so fortunately supplied with so important a remedy for so extensive an evil by the introduction so extensively of the eucalyptus trees from Australia.

OVER 100 liquor dealers in Portland have taken out licenses under the high license ordinance.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, January 2, 1884.

At a meeting of the Board of Directors of the above named company held this day, Dividend No. 63, of twenty-five cents (25c.) per share, was declared, payable on SATURDAY, January 12, 1884, at the office in this city, or at the Farmers' Loan and Trust Company, in New York.

WILLIAM WILLIS, Secretary.

OFFICE—Room No. 29, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending December 31, 1883, the Board of Directors of the German Savings and Loan Society has declared a dividend on Term Deposits at the rate of four and thirty-two one hundredths (4 32/100) per cent. per annum, and on Ordinary Deposits at the rate of three and six tenths (3 6/10) per cent. per annum, payable on and after the 2nd day of January, 1884. By order,

GEO. LETTE, Secretary.

QUICKSILVER.

THE CELEBRATED A BRAND.

Shipped Direct from the New Almaden Mine,

NEW ALMADEN, SANTA CLARA COUNTY, CAL.

J. B. RANDOL, 320 Sansome Street, S. F.

[P. O. Box, 2548.]

ELLIOT'S PURIFIER
FOR
STEAM BOILERS.

(PATENTED FEBRUARY 6, 1883.)

A—Boiler. D—Settler.
B—Feed Pipe. H—Legs to Settler.
C—Overflow Pipe. E—Blow-off Pipe.
G—Funnel. F—Check Valve.
K—Water Line.

A represents the steam room in the boiler.
B represents feed pipe, feeding by spray or otherwise, through the top of the boiler.
C represents the drip funnel conveying water to the settler D.

E represents the blow-off pipe to be used for cleansing the settler when required.
F represents the overflow pipe through which the water flows into the boiler after purification.
G represents the check valve opening upward, so that it will close when blowing off the settler.

H H represent the legs of the settler.
K represents the water-line in the boiler.
The drip funnel is on a higher level than the overflow pipe, causing the water to flow through the settler by gravitation.

The overflow pipe reaches down half-way into the settler, so as to trap the scum and oil, and to retain it until blown off through the blow-off pipe.

This device is warranted to keep the boiler from scaling; will cause all the old scale to come off; will in all cases prevent foaming, and will absolutely prevent explosions. It will prevent foaming, because no air will go into the water in the boiler; and the water fed to the boiler will become perfectly purified before mixing with the water in the boiler.

It will prevent explosions, because no scale will form in the boiler on the fire surface, thereby saving the iron from becoming heated to a red heat, as the water will be constantly in contact with the iron of the boiler.

The connection pipes of the glass water-gauges will not be clogged, because there will be no scum in the boiler to get into them.

There will be no leakage of the boiler from unequal expansion and contraction caused by cold water coming in contact with the iron of the boiler, as all the water upon entering the boiler will be of an equal temperature with that contained in the boiler. This is one of the great features of this invention, as all experienced engineers know who have been troubled by leaky seams and loose rivets in the boiler caused by cold water.

The advantages claimed for this invention are:
1. Simplicity.
2. Its efficacy without the aid of chemicals.
3. It causes no waste of space.
4. It utilizes the heat in the boiler which exists in it, except for the supply of steam.

5. It saves fuel by maintaining the fire surface and tubes clean.

6. It allows the boiler to perform its function without interruption.

7. It saves the trouble of cleaning the boiler by acting automatically.

8. It not alone eliminates impurities held in suspension, but also scum and fatty matter, which are lighter than water.

9. It supplies the boiler with water of a permanently equal temperature.

10. It will prevent the leaking of boilers.

11. It absolutely prevents foaming.

12. It prevents explosions.

CHARLES ELLIOT,

Inventor and Patentee.

OFFICE, 432 Montgomery St., San Francisco, Cal.

DIVIDEND NOTICE.

OFFICE OF THE

Bulwer Consolidated Mining Company.

San Francisco, January 10, 1884.

At a meeting of the Board of Directors of the above named company, held on the 15th inst., Dividend No. 19, of ten cents (10c.) per share, was declared, payable on Thursday, January 31, 1884. Transfer books closed on Wednesday, January 23, 1884, at 3 o'clock p. m. This dividend is payable at the office in this city on all stock issued here and at the Farmers' Loan and Trust Company in New York on all stock issued there. WM. WILLIS, Sec'y.

OFFICE—Room 29, Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

Annual Meeting—Office of the Albion Consolidated Mining Company, room 26, Nevada Block, 309 Montgomery St., San Francisco, Jan. 14, 1884.

The Regular Annual Meeting of the Stockholders of the Albion Consolidated Mining Company will be held at the office of the Company, room 26, Nevada Block, 309 Montgomery St., San Francisco, Cal., on WEDNESDAY, the 30th day of January, 1884, at the hour of one o'clock, p. m., for the election of a Board of Directors to serve for the ensuing year, and the transaction of such other business as may properly come before the meeting. Transfer books will close on Monday, Jan. 28, 1884, at 3 o'clock p. m.

A. W. HAVENS, Secretary.

THE CLIMAX
FIRE EXTINGUISHER

.....IS THE.....

Only Reliable and Practical Fire Extinguisher Made.

No compressed air; no pressure on the tanks, therefore no danger of bursting. No corroding; no expensive chemical. Can be replenished without any delay, and the greatest advantage over all is

NO FAILING IN TIME OF NEED.

California Fire Apparatus Manufacturing Co.

GIANT POWDER,

MANUFACTURED under ALFRED NOBEL'S original and only valid Patents for NITRO-GLYCERINE POWDERS, which has been and still is of such immense advantage to the Miner, Railroad Man and the Engineer. All other Nitro-Glycerine compounds are simply imitations and adulterations of the original Giant Powder.

THE GIANT POWDER COMP'Y

Manufacture THREE GRADES OF POWDER, which are the

SAFEST AND STRONGEST HIGH EXPLOSIVES IN THE MARKET.

THE ORIGINAL NITRO-GLYCERINE COMPOUND.

Ciant Powder or Dynamite,

Is acknowledged by all the Great Chemists of the World as Unapproached by any other Compounds.

The GIANT POWDER COMPANY have acquired the Exclusive Right to Manufacture

“NOBEL'S EXPLOSIVE GELATINE,”

Which contains **96 Per Cent of Nitro-Glycerine.** It is still STRONGER THAN DYNAMITE, and even SAFER IN HANDLING. This explosive was used in constructing the Mont Cenis Tunnel.

The Judson Powder

Is a Black Powder Owned and Manufactured by the

GIANT POWDER CO.

Is from THREE to FIVE TIMES STRONGER than Ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it

Breaks More Ground, Pulverizes Better and Saves Time and Money.

The only difficulty heretofore experienced by some consumers of this Powder has been that it required more time to get it to the bottom of a deep borehole. This has now been entirely overcome, and our

JUDSON IMPROVED

Is now as DRY AS THE ORDINARY BLASTING POWDER and Runs as Freely.

MINING DEBRIS.

Full Text of the Decisions of Judges Sawyer and Deady.

The Points at Issue Legally Explained.

We give below the decision by Hon. Judge Sawyer, and the concurring opinion of Hon. Judge Deady which declared that hydraulic mining, as at present conducted, must be stopped. As this decision is important and far-reaching, both in its direct and indirect influences, we take occasion to present the decision to our readers in complete form.

Decision of Judge Sawyer.

By the Court, Sawyer, Circuit Judge. This is a bill in equity to restrain the defendants, below several mining companies, engaged in hydraulic mining on the western slope of the Sierra Nevada Mountains, from discharging their mining debris into the alluvial of the Yuba River, and into the river itself, whence it is carried down by the current into Feather and Sacramento Rivers, filling up their channels, and injuring their navigation; and some times, by overflowing and covering the neighboring lands with debris, injuring and threatening to injure and destroy the crops and property of the owners, situated on and adjacent to the banks of these watercourses.

REPORT OF LIEUTENANT-COLONEL MENDEL.

In March, 1884, the Secretary of War transmitted to Congress the official report of Lieutenant-Colonel Mendel, of the "corps of engineers upon examinations and surveys to devise a system of works to prevent the further injury to the navigable waters of California from the debris of mines flowing from hydraulic mining," which surveys and report were made in pursuance of the Act of Congress, relating to rivers and harbors, of June 14, 1859. This report, made in January, 1882, was introduced in evidence, and it has been quoted and recognized by both sides in the case, as showing the injurious results of hydraulic and other mining, up to its date, and the remedies attempted and suggested. It is, also, fully confirmed by the other evidence in the case, and by the condition of things as disclosed upon actual inspection and observation, made by the judges who traversed and examined the country affected by the operations complained of, in the presence and with the consent and representatives of the respective parties and their counsel. Many of the facts in the general statement will, therefore, be taken in a condensed form in this report.

HYDRAULIC MINING.

Hydraulic mining, as used in this opinion, is the process by which a bank of gold-bearing earth and rock is excavated by a jet of water, discharged through the converging nozzle of a pipe, under great pressure; the earth and debris being carried away by the same water, through sluices, into discharge on lower levels into the natural stream and watercourse below. Where the gravel or other material of the bank is cemented, or where the bank is composed of masses of pipe-clay, it is shattered by blasting with powder, sometimes from fifteen to twenty tons of powder being used at one time to break up a bank. In the early practice of hydraulic mining, as in 1859, the water was discharged through a rubber or canvas hose, with nozzles of not more than an inch in diameter; but later, upon the invention of the "Little Giant" and the "Monitor" machines, the size of the nozzle and the pressure were largely increased, till now the nozzle is from four to six inches in diameter, and discharges from five hundred to one thousand inches of water under a pressure of from three to four or five hundred feet. For example, an eleven-inch nozzle, at the North Bloomfield mine, discharges one hundred and eighty-five thousand cubic feet of water in an hour, with a velocity of one hundred and fifty feet per second. The excavating power of such a body of water, discharged with such velocity, is enormous; and, unless the gravel is very heavy or firmly cemented, it is much in excess of its transporting power. At some of the mines, as at the North Bloomfield, several of these monitors are worked, much of the time night and day, the several levels upon which they are working being kept constantly illuminated by electric lights, the electricity being generated by water power. A night scene of the kind, at the North Bloomfield mine, is in the highest degree weird and startling, and it cannot fail to strike strangers with wonder and admiration. The amount of debris discharged into the rivers by these operations can only be duly appreciated by actual observation.

THE YUBA RIVER.

The Yuba River is a tributary of Feather River, entering it at Marysville, thirty miles above the mouth of the Feather, where the latter joins the Sacramento. It is the fourth river in size in the Sacramento Valley, and drains about thirteen hundred and thirty square miles of the western slope of the Sierra Nevada Mountains, comprising portions of Sierra, Nevada and Yuba counties—its extreme breadth being about thirty-six miles, and its extreme length about sixty miles, excluding the headwaters of its tributaries. From the foothills to its junction with Feather River at Marysville, the elevation of the Yuba basin above the water is from two hundred feet at its lowest parts to about eight thousand feet at the summit of the mountains; but the gold deposits of this basin only extend to an elevation of from four to five thousand feet in a belt from forty to fifty miles wide. The upper portion of the river is divided into five principal branches, the North, Middle, and South Yubas, and Deer and Dry Creeks. The first four—Deer Creek being nearly as large as the smallest main branch—unite in the mountains before reaching the valley of Deer Creek, and form the last, Dry Creek, joining the main river in the valley, shortly after it leaves the foothills. The debris complained of is mostly discharged into the Middle and South Yubas and Deer Creek, and their numerous smaller tributaries.

DEPOSITS ON THE SAN JUAN RIDGE.

The auriferous deposit on the San Juan Ridge, between the South and Middle Yubas, embracing most of the main branch, and a larger part of the mines now actually worked belong under their

control, is much the largest and most important in the State, and is favorably situated for working. The debris of the auriferous deposits in which it lies being elevated several hundred feet above the beds of the Yubas and their tributaries, and the annual floods of the Yuba may be relied on to carry off a large portion of the debris resulting from mining. Says the report referred to: "The floor extent of the gravel channel and its branches on this ridge is about twenty-five miles. Debris is literally falling from the portion already worked, and for that too deeply covered by lava to be available for hydraulic mining, there remain, probably, not less than four or five miles of channel available for washing, from which only a comparatively small portion of the top gravel has been removed. Below San Juan the gravel body has a surface width of over a mile and a half, and is, say, one hundred and forty feet deep. From Baker Hill to Bloomfield, it is for the greater portion very much wider and deeper. At Columbia Hill its surface width varies from three thousand to four thousand to eight thousand feet, and it is from three hundred to six hundred feet deep. The gravel on this ridge is probably three hundred or four hundred feet deep. At North Bloomfield it is open to the bedrock, showing a depth of more than three hundred feet. Roughly estimating the average width of the remaining gravel range at four hundred yards, and, after allowing for the portion worked off, placing its average depth at twenty yards, the surface width at fifty miles, fifty miles per mile, or for fourteen miles, say seven hundred million yards."

RESULTS OF DEBRIS.

"Allowing for the amount washed since 1876, one hundred million yards, there remain six hundred million to be removed," adding to this the estimated amount still remaining to be worked at Smartsville, lower down the river, and the amount remaining to be washed will appear, says Colonel Mendel: "Seven hundred million of cubic yards may be assumed to represent the amount of gravel remaining to be worked off by hydraulic process, tributary to the Yuba." Approximately, then, according to the evidence, over one hundred million of cubic yards in the debris have been washed out by the hydraulic process, and the debris deposited in the Yuba and its tributaries; and seven hundred million more remain to be washed out, and its debris deposited in these watercourses in the same manner.

RESULTS OF WASHINGS.

The following shows some of the results of former washings, and unmistakably indicates what must result from a continuance of the work: The Yuba with its branches, and small tributaries, were necessarily characterized by heavy grades, the waters falling about eight thousand feet in a distance of ninety or a hundred miles from their extreme sources to the Feather River. They ran through steep, rocky canyons and gorges, over a rough rocky bottom, with frequent rapids, and waterfalls of greater or less height, and there were many deep bays excavated by the action of the water at the foot of falls, rapids, and the like. The debris of all these streams, from the very depths of the higher mines to the junction of the main Yuba with Feather River, a distance of seventy-five miles or more, have all been lifted up many feet deep—it some places to the depths of one hundred and fifty feet, and all the streams have regularly graded themselves, so that a railroad track might be laid upon their beds for the whole distance, the grade, of course, being steeper in the upper part, but equally regular.

BRANCHES OF THE YUBA.

Thus the main branches of the Yuba and Deer Creek, Shady Creek, Bloody Run, Grizzly Canyon, Humbug Canyon, and the other smaller tributaries, all exhibit this result. There are many square miles, in the aggregate, in the beds of these streams, during many feet deep with debris, and these channels are choked and clogged with it—the heavier material being deposited higher up and the lighter passing farther down. Most of it will from year to year be carried farther down, and ultimately down its way to the valley. The transporting capacity of the water, however, is unequal to the task of carrying off all the debris at once, as it is discharged into the stream. So, also, the ordinary floods, from year to year, are unable to carry off all the debris discharged into the streams during the year; and it, consequently, accumulates from year to year. The upper portions of the watercourses, within the mountains, till an extraordinary flood comes. When such a flood occurs, it transports a much larger amount at once, and precipitates it upon the valleys below.

FUTURE DANGER.

Vast amounts are now accumulated in the upper courses of the Yuba and its branches, which are liable to be precipitated in immense quantities into the valleys below, by any extraordinary flood—such as that of 1862—that may hereafter occur. With reference to the amount of these deposits remaining in the Yuba, above Marysville, Colonel Mendel, in his report, says: "The estimates by Mr. Manson, reported to the State Engineer, give the estimated deposits, in 1879, on the Yuba, above the foothills, as for six million four hundred and sixty-two thousand one hundred cubic yards, the gravel bulk to eight or ten miles; and below, twenty-three million two hundred and eighty-four thousand—a total of seventy-one million seven hundred and forty-six thousand one hundred cubic yards. In the light of later information, it seems probable that this estimate is altogether too low. The debris in small tributaries not having been taken into account, and the amount in the lower river having been much underestimated. The actual amount is not capable of being ascertained, and the statements are given merely for the purpose of illustration."

DEPOSITS ON PLAINS.

"At its escape from the mountains, where the foothills recede and give width to the plain, the Yuba spreads out its load of sand and gravel over a plain of fifteen thousand to sixteen thousand acres, which has risen to ten thousand above the level of the adjoining country on either side. This plain has a slope of about ten feet to the mile, varying above and below to the river as you ascend or descend, the slope of the river bed being a little less than the foothills and here feet at Marysville, ten miles below. The size of the material have some correspondence to the grades. Ascending the stream, one passes to a continually increasing average size of material. While it is nearly all sand below, above it becomes nearly all gravel, with, however, considerable admixture of finer material. This is the debris of the mountains has destroyed thousands of acres of alluvial land. The State Engineer, in 1880, estimated that fifteen thousand two hundred and twenty acres had been seriously injured by these deposits from the Yuba.

"On the Yuba, the great deposits of gravel are found on a grade of thirty feet to twenty feet, to the mile. The sands predominate greatly in slopes of ten feet and below."

VALLEY RIVER COURSE.

The portion of the valley here referred to as covered with sand is that portion of the borders of the Yuba River extending across the Sacramento Valley from the foothills to its junction with Feather River at Marysville—a distance of about twelve miles. Formerly, before hydraulic mining operations commenced, the Yuba River ran through this part of its course in a deep channel, with a gravelly bottom from three hundred to four hundred feet wide, on an average, with steep banks from fifteen to twenty feet high at low water, on either side. From the top of the banks, on each side, extended a strip of bottom lands of rich, black, alluvial soil, on an average a mile and a half wide, upon which were situated some of the finest farms, orchards and vineyards in the State. Beyond this first bottom was a second bottom, which extended some distance to the ridge of higher lands, the whole constituting a basin between the higher lands on either side, of from a mile and a half to three miles wide. Not only the channel of the river through these bottoms, but the strip of bottom lands on either side, and the strip of bottom lands on either side, were all covered with a layer of gravel and sand, many feet deep, from ridge to ridge of high land, and utterly unfit for farming and other purposes to which it was before devoted, and has consequently been abandoned for such uses.

DR. TEGARDEN'S RANCH.

Dr. Tegarden's ranch affords a very striking example of individual injuries indicated by this mining debris. Dr. Tegarden is a prominent citizen of Yuba county, having for some years represented the county in the State Senate. He owned twelve hundred and seventy-five acres on the Yuba bottom, some three or four miles above Marysville, on the north side. All, except the seventy-five acres now lying outside the levee, have been built up from three to five feet over with sand and gravel, deposited for farming purposes; for which industry he has received no remuneration. He now lives in a small house near the levee, on the outside, which is made to be swept away should the levee break opposite to him during an extraordinary flood. Dr. Tegarden testifies that the main thing up was in 1879, but that there had been a constant addition to it ever since, and that, during the last year, it has filled up faster than in any other time; that he built two miles of levee to protect it, but it proved inefficient; and that the land is five to six feet higher with sand and sediment on the river, or inside of the levee, than the land on which he lives. A considerable portion, but not all, of the lower bottoms of the Yuba were covered by the accumulation of debris brought down by the great flood of 1862; but it has been extending and deepening ever since. Much, perhaps most of it, was more or less covered by 1865 or 1869. Since that time it has been built up by the debris of the Yuba and Yuba county, which has been carried down the river for the purpose of protecting the lower portion of the elevation, and for the protection of Marysville and the adjacent country.

LEVEE PROTECTION.

In addition to the levees so erected five years ago, as O'Brien, who did the work, testifies, the miners themselves also built a levee for the same purpose, being the levee on the south side of the Yuba, from the foothills to the Headwaters, with which it connected at Heiges station, a distance of eight miles, at a cost of \$66,000, or which sum the defendants in this suit paid 80 per cent. This is the levee which, connected with the grade levee on the north side, protected the river from overflow on the south. It broke in three places in Lincoln township, in June last, when the Eglisio dam gave way, and the country for a considerable distance below, extending to the Eliza tract, several miles distant, was flooded, with some though not great damage to the crops. The river, however, having soon passed itself. Not only has all the space between these levees been filled with the debris to a level with the high lands upon which they are built, but for miles of the lower portion of the river, the filling, between the levees, is several feet above the level of the surrounding country on the outside. The levee on the north side is grown up with young cottonwoods and willows.

NO DEFINITE RIVER CHANNEL.

The river has now no definite channel within these bounds, but runs everywhere over the space between the levees, alternate two to three miles apart, according to the obstruction its waters meet from time to time by growing trees, or accumulation of drift-wood, or deposits made by itself, thereby raising the bed, where it actually, for a time, runs to a higher level than the bed of such surrounding channel as it has. This broad channel, or bed, such as it is, is several feet higher than the lands of the surrounding country outside the levees, which outside lands have no protection from overflow of the river. The Yuba, surcharged with debris, except the slender intervening artificial banks, so erected by the people and the miners for that purpose. The lands thus already buried and destroyed are over fifteen thousand acres, or twenty-five square miles; or, taking the average width, a tract from the foothills to Marysville, of from a mile to two miles wide, of from two to three miles deep. The filling in the river bed is generally twenty-five feet or more, and at its immediate junction with Feather River at Marysville, is about twenty feet deep—some witness a make it deeper—where it forms a bar of nearly that depth across Feather River. The depth of the filling is increasing year by year, and raising the bed of the river within the levees higher and higher above the surrounding country outside the levees. The depth of the filling increases as the river is ascended, till, at Squaw Flat, near Park's Bar, below Smartsville, at the entrance of the foothills, according to the testimony of O'Brien, a witness for the defendants, it is from fifty to sixty feet deep. Opposite Success Flat, above Smartsville, and at the narrow above Smartsville, sixty feet deep. The deposits constituting the first fifty feet, at Squaw Flat, have been there ten or twelve years, and the rest has accumulated since. At a point near this, at Rose's Bar, where the levee was once one hundred feet high, it has now been raised to the level of the canyon, it has now been raised by filling to a level of three thousand feet wide. But at these points no valuable lands are covered.

THE EFFECT UPON NAVIGATION.

The result, as affecting the navigability of the waters of the State, will be stated upon the authority of Mendel's report, which was made upon instrumental surveys and actual measurements, and is amply supported by other evidence. The low-water level of Feather River, at Marysville, the head of navigation, has been raised fully fifteen feet—at this time more—indicating a rise of the bed of the river to that height above its former bed. At the mouth of the river, at its former bed, it is fully five feet. Says Mendel: "Taking fifteen feet at Marysville and five feet at the mouth, the difference—ten feet—is to be added to the old fall. This increases the slope of the Feather, in its navigable part, four inches to the

mile. This increase has impaired the depth of water and the practicability of navigation to a considerable extent."

"Applying to the navigable portion of the Feather the rule accepted for the minimum deposit in the Sacramento, namely, that the average flow is equal to the elevation of the plane of low water, we will have, for the thirty miles from Marysville to the mouth, an average depth of ten feet over the bed of the river. This estimate is thought to be here as in the Sacramento, considerably below the fact." Some witnesses say it is now fifteen feet. Again: "As a consequence of these changes, a higher flood line and greater exposure to overflow now exists for all riparian lands on both these rivers. This is an element of considerable loss to the country, but its description and discussion do not come within the limits of this investigation."

RIVER BEDS.

"The elevation of the bed of the river is not accompanied by an equal rise in the level of the banks. The level of the bed approaches more and more the level of the banks. In the cases of the Yuba and Bear, non-navigable streams, the level of the beds has risen from a depth of a number of feet below the banks to an elevation of several feet above the banks."

"These instances may be taken to illustrate the ultimate condition of the Sacramento and Feather River, under a continuance of the influence to which they are now subjected. The probability of this result is a consequence of the fact that the debris is carried by the river, and the testimony on the point is conclusive, that there is no river of the Sacramento leaving its channel at Gray's Bend, and running some distance from Sacramento city to the west."

"In the Sacramento River, a similar rise in its bed has taken place, from the fact that, during the first ten years of mining, from 1849 to 1859, the low water plane in the river at Sacramento, was raised two and three-tenths feet. During the next ten years of hydraulic mining, from 1859 to 1869, the rise in this plane was doubled. It has raised fully six feet from 1849 to 1869. Says Mendel: "As a consequence of the elevation of the bed, the level of the river, in 1849 extended at least six miles above the mouth of the Feather, twenty-five miles above Sacramento, and was quite two feet at Sacramento, is now no longer noticeable above Headwaters, one mile below Sacramento. The tide, within the past thirty years, rose on these shoals as much as three feet."

BELOW SACRAMENTO.

"Twenty-five miles below Sacramento the river divides into two main channels, which unite below, the intermediate distance by the two channels being eleven miles by Old River and twelve miles by Steamboat Slough."

"In the earlier days of mining, and until six or eight years ago (about 1853), Steamboat Slough was the channel used by all boats and vessels."

"It is a part of the public history of the State, with which all the early settlers are familiar, that for years the comparatively deep channel of Steamboat Slough, and the river of the Sacramento from New York to Portland, Maine, and farther to run on the Atlantic Ocean out of New York, both of which either came round Cape Horn, or through the Straits, ran regularly through Steamboat Slough. This slough is now filled up, so as to be navigable for the lighter craft, and boats to use the shortest and easiest route, and the debris of the debris of the river have not only been filled and raised for several feet, but the channels have been largely contracted in width. So, also, from similar causes, the shoal water in Suisun, San Pablo and San Francisco bays, and in the adjacent waters of the bay, have been raised, and the navigable channels of these waters have been considerably and materially contracted. The debris from the river and the American of course could not be used to fill the Sacramento, below the mouth of the American and Steamboat Slough, as do some of the southern rivers, to avoid the amount of debris which the slough has been carrying down. San Pablo and San Francisco bays, but the debris of the Yuba of course is much larger amount of debris than all the other mines together."

"To speak of remedial means, Col. Mendel says: 'The effect of the case presented in the preceding pages seems to establish the necessity of measures to be taken to prevent, even in the event that no further contribution be made to mining debris, to the beds of streams.'"

RE-TRAINT UPON MINING DEBRIS.

"The preservation of river-beds and routes of drainage requires that effective restraint be imposed upon mining debris. Otherwise, these drainage lines may be expected to suffer the fate which overtook their prototypes, the Placocene rivers, which were obliterated by enormous deposits brought down by their own currents."

"It may be added that the conservation of existing facilities for navigation equally requires restraint of the flow of sand and gravel; and that no improvement of the channels can be expected until this result shall be secured. Under all circumstances, the great and essential step to any project, whether of alleviation, conservation, or improvement of."

"It has been shown that in the beds of the American, Bear and Yuba there are now lying many millions of cubic yards of material in positions where it is comparatively harmless, and that, each year, as a rule, adds something to the volume of these deposits, but that, whether anything is added or anything is subtracted, which is sometimes the case, depends upon the volume and power of the floods. As a rule, the mines supply more material annually than the floods are able to transport over the grades in the lower portions of the rivers. If the floods were of sufficient duration, the accumulations would be found lower down and in more dangerous positions. Instead of lying in the bed of the Yuba, they would be in the Feather and Sacramento."

"The waters of the Yuba are so charged with debris that they are wholly unfit for fishing, or for any other use, except the use of the water, which water is usually applied, without doing first taken out of its stream and allowed to stand to some unpolluted place and settle. As it comes down to Marysville, it is so heavily charged with sand as to render it unfit even for surface irrigation."

THE DRAINAGE ACT OF 1859.

In pursuance of the provision of the drainage Act of 1859 (Stats. 1859, 130), the State, under the supervision of the State Engineer and Col. Mendel, as consulting engineer, erected a brush dam for accumulating debris, about two miles to the north, across the Yuba River, from the ridge of high land, some eight miles above Marysville. At the ordinary flood in the following rainy season, a large section on the northern end and two other sections towards the south were swept away. According to the report of Hamilton Smith, its engineer, to the North Bloomfield Company, made in July, 1881, after the great flood, the dam was at its greatest height, fourteen feet. Its cost, being in the neighborhood of one hundred and twenty thousand dollars, and it broke in three places, as follows: "The east embankment at the northern end and

gish chancery reports, largely in relation to the sewage of large cities, towns or other organizations having the matter in charge, where these bills have been authorized by acts of Parliament to construct sewers and discharge the sewage into the streams, which, when constructed, created nuisance to land below; and in such cases it has been held that they took notice by implication, one must be limited to the acts clearly authorized, and that they could not create a nuisance as a desired object by the acts expressly authorized without creating a nuisance, they would be restrained. Although Parliament, being competent in its legislative capacity, could authorize nuisances or the taking of injury to private property, and the making of nuisances, it is not a duty on the Courts to do so, and the Courts were still more careful not to imply or infer authority to create nuisances not clearly given in terms by the Act. The following are some of the cases referred to: Attorney-General vs. County Hatch, 14 Jurist 451; Attorney-General vs. Chappell, 11 Jurist 481; Attorney-General vs. Farnham, 11 Jurist 481; Attorney-General vs. Birmingham, 4 Kay & J. 528; Attorney-General vs. Seed Corporation, 5 Id., 583.

The first observation suggested is, that none of these provisions, either State or national, has any relation at all to the subject-matter of the suit. They simply recognize and legalize custom and regulations by which miners' rights, as between themselves, upon the public lands may be secured, regulated and protected. They relate to "mining claims" alone—to the manner of acquiring and protecting rights in them. They refer to the extent of the claim, the number of tailing up a claim holding it, the evidence of title, etc., as between themselves and as against each other, and are not at all applicable to the rights of the Government or owner of the land. Much less do they attempt to give them rights as against private parties, vested with the fee of other lands in mining, and not even within the mining region. It has no relation to lands owned in fee by private parties. The principle acted upon was, that the Government owned the land, and that the owner of the lands in which the mines were found, as the proprietors of limited portions of the mines on the public lands actually in the possession and occupation, and to prescribe rules for the acquisition, regulation and protection of such limited rights. The principle was, that the State, under reference to other public lands in *Lamb v. Bavenport*, 18 *iw.* 620, and this statement of the principle was approved by the Supreme Court of the United States in *Star v. Star*, 94 *U. S.* 437, *note*. The provision to no way interfere, or attempt to interfere, with the rights of the owner of the fee of other lands, is equally less in any other lands; nor does it authorize, or attempt to authorize, any custom, or usage, or regulations which shall encroach upon the rights of others owning agricultural lands in fee, situated in the valleys many miles distant. On the con-

itary, it is expressly provided, that "such customs, usages, or regulations shall govern" only "when not in conflict with the laws of the State." A custom or usage attempted to be established, whether by minor or by a majority of the people, or by the majority of the lands of private owners, holding titles in fee from the Mexican Government, as old as the title of the United States, without first acquiring the right to do so by purchase or other lawful means, upon compensation paid, would be in direct violation of the laws of the State and of the United States, and of the Constitution of the United States. It would also be in direct violation of the express provisions of the statutes defining nuisances already cited.

AN AXIOM.

One of the earliest statutes passed by the first Legislature of California, adopted the common law as the rule of decision in this State; Stat. 1850, p. 219; and that statute has been in force ever since, except so far as modified by the Civil Code. *Sic utere tui alienum non leas*, is one of the fundamental maxims of the common law, more frequently cited and enforced, perhaps, than any other in the law. And this maxim is contained in force in Sec. 354 of the Civil Code of California, where it is translated: "One must so use his own rights as not to infringe upon the rights of others." Any custom, or usage, which would attempt to authorize the acts complained of, would directly violate this fundamental principle of the law. As we have said, it is in common law upon some very remote considerations of an act, the Judge observed that this rule was too indefinite to furnish a certain rule to be guided by in many cases; and it was insisted by counsel that it really had little significance or value; but this case does not lie so near the line of distinction as to call in doubt as to its application. No possible refinement or legal hair-splitting can exclude it from the operation of the rule. It is obviously within the rule, and so far from the horrors as to leave no possible ground for doubt as to its applicability.

THE OLD AND NEW STATE CONSTITUTIONS.

The first section of both the old and new State Constitutions provides, that "all men * * * have certain inalienable rights, among which are those of * * * acquiring, possessing, and protecting property." These rights must necessarily include the right to enjoy, without let, hindrance, or obstruction by others, the property so acquired, possessed, and protected; and is not competent for the Legislature to authorize any encroachment upon the rights of one class of citizens by custom or usage adopted by those pursuing any particular class of industries. Again, as we have already seen by other constitutional provisions, it is provided, that "private property shall not be taken or damaged for public use without just compensation having been first paid therefor," and "no person shall be deprived of his property without due process of law," and the same inhibition is put upon the States or the amendments of the National Constitution.

CUSTOM AND USAGE.

The customs and usages relied on would be in direct conflict with all these provisions, and consequently, if any such there are, they can not be valid. The customs recognized and validated by Congress are only the same "local" customs here recognized by the State legislation, except that the Acts of Congress not only regulate these matters among miners as between themselves, but also give them some rights as against the United States in the public lands, but in no other lands, and the limitation expressly put upon these customs and usages is, that they shall not be "in conflict with the laws of the United States or the State * * * within which the district is situated." Thus Congress is also careful not to give any countenance to the idea that private rights can be encroached upon under the guise of the customs or usages of miners, intended to be legalized. Again, such customs and usages recognized are "local" customs limited to the "bar or diggings" within which they are situated. They are not general customs, and such customs and usages are never up in this particular are not within the legislation invoked. Besides, customs to be valid under the common law must be reasonable. Can a custom or usage which should allow the whole valleys of California to be filled up and devastated, no matter how well improved or far they are, be reasonable? Such a custom would be valid if the custom relied on is valid. It is only a matter of degree, not of principle. The Supreme Court, in the *California* case, recognized the validity of any custom to mine in such a manner as to destroy or injure the property of others, even in the districts or diggings where the local customs and usages of miners are sanctioned by the statutes. But the California reports are full of cases, where the principle has been enforced, that the owner of the property must use his own property as not to injure another.

COMMON LAW AS TO WATER RIGHTS.

Said the Supreme Court in *Hill vs. Smith*, 27 Cal. 492: "This notion [that the rules of the common law as to water rights have been modified in California] is without substantial foundation. The reasons which should sustain the ground-work of the common law upon this subject remain unimpaired. The conditions to which we apply them are changing, and not the rules themselves. The maxim, *Sic utere tui alienum non leas*, upon which they are grounded, has lost none of its governing force; on the contrary, it remains now, and in the mining regions of this State, as operative as ever. The lawfulness of waters as a right in the past in any other country." And in *Richards vs. Kilgus*, 24 Cal. 74, the Court said: "He is bound to use his property as not to injure his neighbor's land, irrespective of the question as to which has the older right or title, and if through any fault or neglect of his he does not properly manage and keep in repair the water ditches, or overflows or breaks through the banks of the ditch and injures the lands of others, either by washing away the soil or covering the soil with sand, the law holds him responsible; and these are not examples of many others too numerous to mention, and too familiar to the State to require citation. The Supreme Court of the United States recognizes the principle of the maxim also in *Johnson vs. Kilgus*, 10 Cal. 400; and the position of the defendant in that case prevented him from doing this, and thus destroyed his mine claim. No system of law which would allow the owner to tolerate the use of his property in this way so as to destroy the property of another."

We are fully satisfied that the acts of defendants complained of are not authorized by any valid custom or usage, or by any valid law, statute or ordinance, of the State of California or of the United States, and that consequently they are entitled to such relief as shall fully and amply protect them from any further injuries to his property and any further encroachments upon his rights. What shall the remedy be? It would be difficult to appreciate too highly the importance of the mining interests. The fact is patent that immense sums of money have been and are being employed in this branch of industry. The holiness with which capitalists, and especially

these delinquents, have invested large amounts of capital; the perfection to which these enterprises have been carried; the enormous machinery and appliances for successful mining; the vast enterprises they have undertaken and successfully carried out; the energy, perseverance, great engineering and mining skill displayed in pursuing these enterprises, excite wonder and unbounded admiration.

REMEDY FOR THE GRIEVANCES.

In view of these undisputed, indisputable and well known facts, no one could possibly be more averse than we are to applying any remedy to the grievances complained of that must put an end to hydraulic mining, if any other can be devised, or at least none available in the present stage of the case. Two were suggested in Mendocino's report:

1. The purchase of large tracts of low lands in the valleys, which are now, or may be permanently covered with water, without material injury to navigation, or to other property owners, and turning the same into a river, with its banks, into them, using them as settling reservoirs.
2. The building of impounding dams at suitable points on the river to hold back the heavier portions of the debris.

PROPOSED REMEDIES.

The first seemed to be regarded as too expensive to be feasible. The second is the only one suggested and urged in this case, and much testimony has been taken as to the practicability and safety of the plan. As is usually the case, the views of different engineers and experts, distinguished in their professions, differ widely upon the points of practicability and safety. The larger number of witnesses called, and touch the larger amount of testimony, so far as mere opinion goes, are doubters in favor of the practicability, if sufficient means are furnished. But all the practical experiments heretofore made, at great expense, under the supervision of the State and of competent engineers, have been lamentable failures. The dams constructed were, doubtless, in many particulars, defective. But what guaranty have the Court and those whose lives and property are at stake that any future works of the kind will not also be defective? As at present advised, with some knowledge of the operations of the tremendous force of nature, we can not undertake to say, upon the mere opinion of experts, given in reliance, as in this case, upon the competency of the witnesses, would be practicable. We can not defend in advance what works shall be sufficient, and authorize the continuance of the acts complained of upon the performance of any prescribed conditions.

DIFFICULTY OF CONSTRUCTING DAMS.

In view of past experience, here and elsewhere with the damming up of waters, and of the wide difference of opinion of competent engineers on the subject, it is clear that we should not be justified in an attempt to prescribe in advance any kind of a dam under which a large community should be compelled to live, and the dread of a perpetual, seriously alarming, and ever present menace. Even the pure waters of Niagara, within the memory of man, have made a sensible impression upon their bed of competent rock, adapted for its purposes by an almighty and Omnipotent power. Portions of the solid earth from time to time yielded to the force of the mighty flood, and the completed dam, the Court presiding, the author of the article on Niagara Falls, in the *American Cyclopaedia*: "In the short of time hardly reaching back into the last century, during which observations, other than those of passing travelers, have been made and preserved, changes have taken place by the falling down of masses of rocks, the falling of which has been caused a slight recession of the water, when directed the gorge to the same amount upward toward Lake Erie. Thus, in 1818, great fragments descended at the American Fall, in 1838 at the Horseshoe Fall, and since 1855 several others have materially changed the aspect of the falls." *Id.*, p. 418. When Father Hennepin first visited Niagara, in 1679, the falls fell formed on the Canadian side of a huge rock, when divided and carried the current. At the time of the visit of the Swedish naturalist, Kalm, in 1750, the rock had fallen down and left the cataract, in respect to the number of falls, more nearly to its present condition. In 1842 Professor Hall made an exact scientific, trigonometrical and geological survey of the falls, and from his survey, and made a vivid and exact idea has been formed of the enormous mechanical powers which were at work here * * * The fall of water acts as a huge saw, cutting a channel in the rock at the rate of about one foot a year." *Id.*, p. 418.

NIAGARA CONTRASTED WITH YUBA.

These facts forcibly illustrate the tremendous power of the element against which the engineer must contend in his efforts to impound the mining debris. Yet it is proposed to erect a barrier in the narrows of the Yuba, upon a head of debris now sixty feet deep, that out of the foothills, and augmented and deepened, as high as Niagara, over which the water is carried in a narrow gorge, charged at times with great quantities of heavy material, on occasions of great floods will pour in volumes equal, perhaps, or nearly so, to those pouring over an equal space at Niagara. It is also that this proposed dam will be a debris dam, and less dangerous than a water dam. But Niagara cannot be said to be a water dam in any other sense than the one proposed when filled, or nearly filled, with debris. The danger shown by the testimony will be, not so much from the pressure above as from the force and effects of the water greater or less dimensions, falling over and down the dam so great a distance, according to the testimony of Hamilton Smith, the very intelligent, competent and reliable engineer who built the English dam, there were rocks in it of ten tons weight, not a vestige of which could be seen after the breaking of the dam in June last. They must have fallen from the top of the dam down the stream, or crushed to pieces by the overtopping forces brought to bear upon them. And according to the testimony of another witness, who followed down the Yuba to observe the effects of the torrent resulting from the breaking of that dam, rocks of much larger dimensions were exhumed from the bed of the river, had wholly disappeared. The dams would show the enormous resisting power required to render an impounding dam perfectly safe. Engineers, as before stated, offer as to the practicability of building a safe dam at that or other points. We cannot presume to determine the possibilities of constructing dams with "money enough" at command, where distinguished engineers differ in opinion upon the point. It is enough for us to know that the matter rests in mere opinion, and that the opin-

ions of men eminent in their profession are not in accord upon the question. It is obviously impossible that the Court should determine in advance what dams may be built that will be sufficient, or prescribe any conditions upon the fulfillment of which defendants should be permitted to continue the acts complained of.

EFFICACY OF DAMS.

According to the testimony of some intelligent witnesses, only about seven per cent of the debris would be retained by any dam, as all that the water is capable of carrying in suspension would pass over under any circumstances. This percentage of the enormous quantity yet to be mined would add a great deal to the amount now in the stream. A large amount, at all events, would necessarily pass over.

Dams, such as are proposed, properly constructed, and not carried too high, may well be safe, and extremely valuable in keeping back the debris now in the stream, and largely mitigating the injuries now existing and threatened, even though utterly inadequate to protect the valleys below, in case hydraulic mining continued, and enormous quantities of debris be added to that already accumulated. But there are no dams now of any appreciable service in protecting the rights of complainant from further injury, either from the debris already in the streams or such further accumulations as may arise from a continuance of hydraulic mining as now pursued. There is therefore no alternative to granting an injunction.

MINING AND AGRICULTURAL INTERESTS.

A great deal has been said about the comparative public importance of the mining interests, and also the great loss and inconvenience to the defendants if their operations should be stopped by the Court. But we have no concern with the comparative importance of the interests with which we have nothing to do, but simply to determine whether the complainant's rights have been infringed, and if so, afford him such relief as the law entitles him to receive whatever the consequence or inconvenience to the wrongdoers or to the general public may be. To similar suggestions, in Attorney General vs. Council of Birmingham, where the Council of Birmingham, having a population of two hundred and fifty thousand, was the nuisance complained of, the Vice Chancellor said: "Now, with regard to the question of plaintiffs' right to an injunction, it appears to me that, so far as this Court is concerned, it is a matter of almost absolute indifference whether the nuisance is a public one or a private one, or whether it affects a population of two hundred and fifty thousand, or a single individual carrying on a manufactory for his own benefit. * * * I am not sitting here as a Committee of Public Safety, armed with arbitrary power to prevent what, in its view, will be a great injury, not to Birmingham only, but to the whole country; that is not my function." 4 Kay J. 639; see also *S. O. vs. Bandy*, 100 Ala. 1, 17 Heald, 1 R. L. Eq. Cas., 77. So in Attorney General vs. Council of Birmingham, the Vice Chancellor observes: "It is said * * * unless the defendants are permitted to throw all their sewage upon their neighbors' lands, upon which they have no more right to throw it than upon the lands of the plaintiffs, the sewage will [which contained two thousand and two hundred pounds] and, therefore, they contend that they must be permitted to dispose of the whole of the sewage on their neighbors' lands. Surely, the mere statement of the proposition is quite sufficient to refute it. Nobody can suppose the law of England to be in that state. It is not to be supposed that the sewage of Birmingham would in the case of Attorney General vs. Birmingham, that two hundred and fifty people will be made so inconveniently if they are not allowed to use their neighbors' property without paying for it; that on that account they are to use their neighbors' property without paying for it. * * * This Court does not decide what the law is as it exists, but what it is as it is applied to the facts of the case. It is not to be supposed that to order anything done that is impossible, as in the illustration I have given, but to take care, subject to that modification, that persons shall be restrained from exercising with a high hand powers which they have no right in law to exercise." 4 L. R. Ch. App. Cas., 165.

AN ENGLISH CASE.

In these cases the acts causing the nuisance were urged as absolutely necessary to the safety of the people interested—to three hundred thousand people in the case of the city of Birmingham—but the defendants were plainly informed that it was not the duty of the Court to pilot out now the nuisance should be avoided, but that, however necessary to the safety or convenience of those interested in the continuance, they must find a way to prevent the nuisance, or cease to perform the acts which occasioned them. Certainly, the law is not less favorable to the protection of the rights of every man, under the several express constitutional restrictions before referred to in this country, than it is in England, where there are no such limitations on the legislative power of the Government, and where the same effect in our reports. In *Weaver vs. Eureka Lake Co.*, 15 Cal. 274, the Court said: "It is contended that, under the circumstances, the erection of the dam was justifiable and proper, and that the great value of the lakes as reservoirs is a sufficient justification for the injuries resulting to the plaintiff from the dam. No principle of law upon which such a position can be maintained. * * * A comparison of the value of conflicting rights would be a novel mode of determining their legal superiority." And in *Wix vs. the Bear River etc. Co.*, 24 Cal. 373, the Court said: "The four remaining instructions asked of the Court are founded upon the theory that, in the mining districts, the rights of the rights of miners and persons owning claims constructed for mining purposes, are paramount to all other rights and interests of a different character, regardless of the time or mode of their acquisition; thus annihilating the doctrine of priority of cases where the contest is between a prior or different owner, who claims the exercise of any other kind of right, and the ownership of any other kind of interest. To such a doctrine we are unable to subscribe, nor do we think it clothed with a plausibility sufficient to justify us in combining it." But authority is not necessary on so plain a proposition. Of course, great interests in the continuance of the mining, or in the destruction of the property, are not to be considered as a matter of course, but as a matter of course, the rights of the owners of the property are paramount to all other rights and interests of a different character, regardless of the time or mode of their acquisition; thus annihilating the doctrine of priority of cases where the contest is between a prior or different owner, who claims the exercise of any other kind of right, and the ownership of any other kind of interest. To such a doctrine we are unable to subscribe, nor do we think it clothed with a plausibility sufficient to justify us in combining it." But authority is not necessary on so plain a proposition. To such a doctrine we are unable to subscribe, nor do we think it clothed with a plausibility sufficient to justify us in combining it." But authority is not necessary on so plain a proposition. Of course, great interests in the continuance of the mining, or in the destruction of the property, are not to be considered as a matter of course, but as a matter of course, the rights of the owners of the property are paramount to all other rights and interests of a different character, regardless of the time or

hydraulic miners, to send their debris down these rivers regardless of the injurious consequences to the navigability of the subject property.

2. That the defendants have done the acts complained of for so long a time and under such circumstances as to acquire a prescriptive right to continue the same; and

3. That the suit is barred by the Statute of Limitations of the State; Secs. 319, 343, of the Code of Civil Procedure.

In the exercise of his power to regulate commerce and establish post roads, the United States may impair the navigability of a water-course within a State; but it has no power, either as a land owner or sovereign, to impair or obstruct the navigability of such water for the mere purpose of promoting or facilitating the working of mines upon the public lands, either by itself or its grantee.

PRIVATELY NOT CONFERRED BY THE UNITED STATES.
The United States has not attempted nor intended to confer upon the defendants any right or privilege to locate or fill the waters in question, or to in any way injure the property of another or impair the use or enjoyment thereof as a water-course for the mining of other persons. The Act of July 9, 1866, 15 Stat., 231, and the Act of July 9, 1870, 16 Stat., 217, and May 10, 1872, 17 Stat., 97, in making the public lands public, and the public lands and to provide for their sale under certain circumstances, subject to the power of the State to make rules concerning "encroachments and drainage necessary to their complete development." But this latter clause does not confer any power over the subject upon the United States which Congress did not possess. Indeed, it is only a prudential declaration of what there ought never to have been any doubt about, that the sale of the United States to the purchaser did not prevent the State from exercising whatever police power it may of right have over the subject.

The State has no authority to allow the defendants to use these waters or the adjacent lands, for the purpose of depositing therein or thereon their mining debris, otherwise than by Secs. 1, 2, 3, subdivision 5 of the Code of Civil Procedure, which provides that "dumping places for workable mines" and "other natural or otherwise" for the flow of tailings may be taken under the right of eminent domain as for a public use.

AN UNCONSTITUTIONAL PROVISION.
The Supreme Court of the State has already decided that this subdivision 5 is unconstitutional when applied to a case of a single person seeking to condemn private property, as a dumping or depositing place for mining debris. It is difficult to see on what ground a taking of property by any number of persons for such a purpose can be held to be a taking of private property for a public use. But that as it may, this section does not authorize the defendant to use the plaintiff's lands, or the easement appurtenant thereto, as a dumping or depositing place for the tailings from their mines until the same has been duly condemned for that purpose and compensation made to the owner.

By Sec. 3 of the Act of 1872 the State into the Union, 18 Stat., 452, it is declared, "that all the navigable waters within the State shall be common highways." These words mean anything, the State is authorized to restrict or prohibit or authorize obstructions to the navigation of the Father and Sacramento, which shall prevent their being used as common highways, according to their capacity and condition when the State was admitted. See Hatch vs. Willmet Iron Bridge Company, 7 Saw., 127.

THE DEFENDANTS HAVE NO PRESCRIPTIVE RIGHT.
The defendants have no prescriptive right to do the acts complained of.

And, first, there is no such continuity of possession, occupation, or use between these defendants and the many persons who may have preceded them in the occupation of the lands, and the mines in this region, as to constitute a similar wrongful act as to the injury of the plaintiff, or his co-defendants, so as to entitle them to claim the benefit of such acts or the time occupied by them in support of their plea for prescription. But, as the rule is, that the use of an easement for such time as the statute makes an adverse possession a bar to the recovery of the same, if the premises establish a prescriptive right thereon, this question is not material, as the defendants appear to have been in the use of the rivers and adjacent lands for the flow and deposit of their tailings for five years before the commencement of this suit. But this is a public nuisance. No one has the right to create a nuisance to come to a public nuisance against the public; and I think the better opinion is, that an individual who sustains a special injury from such nuisance may maintain a suit for its abatement or an injunction to restrain its further commission without reference to the lapse of time.

ACQUESCENCE.
But it is essential to a prescriptive right to an easement in or upon the property of another that the owner should acquiesce in the use. While five years' uninterrupted use of the waters of the Yuba and Feather by the defendants, as a place of flow and deposit for the debris of their mines, so as to fill the channels to a depth of no more than two feet, might, under some circumstances, be sufficient evidence of an acquiescence in such use by the plaintiff, it is not evidence of his acquiescence in the use of such waters for that purpose, so as to fill the channels to a depth of eleven, twelve, or more feet. The difference of one foot in the channels is a vast difference, and the result to the plaintiff, both as to the navigability of the rivers and the depth and extent of the consequent overflow and deposit on the adjacent lands.

In the case of a continuing and increasing trespass, it would be both illogical and unjust to infer an acquiescence in the latter and more injurious act, merely from an acquiescence in the former, in the earlier and less harmful one.

SPREAD OF TAILINGS.
Now, the evidence in the case shows beyond a doubt that the fill of the rivers, and the consequent overflow and spread of the tailings, has increased year by year, for the past ten years. And if the defendants continue to work their mines as they have done, this increase may reasonably be expected to go on from year to year, requiring an additional outlay for the erection and elevation of levees each year, and causing great risk and danger to the persons and property in their vicinity.

There is no direct evidence of acquiescence in this case; and there is really little or no reason in the circumstances for saying that the plaintiff or the community acquiesced in the deposit of mining debris in these waters ever acquired in any proper sense of the term in the good faith of those who have been situated in the latter and more injurious to him and them. Rather, it may be said, that they have borne a burden—not so heavy or dangerous as that, but gradually growing more so, until it has become intolerable—which, owing to the state of things heretofore existing in California, they could not well avoid if they would.

DAMAGE BY WASHING SOIL INTO RIVERS.
But as the developments of later years, following the introduction into the mines of those wonderful hydraulic engines, "The Monitor" and

"Little Giant," throwing a stream of water upon the gravel and sand banks, in some instances of nine inches in diameter, under a pressure of from two hundred to five hundred feet, have shown the serious character of the injury produced, a threefold increase in the production of this liquid and unlimited washing of the mountains into the rivers and on to the adjacent lands, the agricultural and commercial interests and communities are seriously affected thereby have begun to make themselves heard where once the temporary convenience of an individual will of the water was the only law. Since then the persons suffering from this wrong have subjected and prostrate against its continuance in many ways, until finally they have, in the person of this plaintiff, appealed to this Court for the relief to which they are entitled.

There is no statute of limitations applicable to this suit. Sec. 319 of the Code of Civil Procedure of California, created by the defendants, is void in actions involving the right to the actual possession of the time to real property, and not a mere easement in the land of another. When, by lapse of time, accompanied by an undisputed user, a party acquires an absolute right to such easement, he is said to be entitled by prescription.

AN EXPERIMENT.
On the argument, counsel for the defendants insisted that dams could be built on the Yuba, above the valley, as, for instance, at a place called "The Narrows," just above Smartsville, that would prevent the flow of debris from the mines and permanently detain them in the mountain courses of the river; and upon this assumption it was asked that if the Court found that the defendants were committing a nuisance to the injury of the plaintiff, as alleged in the bill, that the Court should not, by its decree, require the defendants to build such dams, but that they should be left to their own devices to build such dams, and in the meantime allow them to operate their mines as at present. In other words, the Court is asked to allow the defendants to continue the commission of the nuisance unrestricted until they can try the experiment of a dam or prevent the nuisance by means of a dam.

In my judgment, this would be a most lame and impotent conclusion from the premises. If the defendants can devise and carry out some lawful plan for impounding their debris in the mountains, they are at liberty to do so, so far as the plaintiff is concerned, but the experiment ought not to be tried at the expense of the plaintiff or by the denial or postponement of the relief to which he is now entitled. The injunction which the plaintiff seeks will not prevent the defendants from building dams, if they are otherwise entitled to do so, or from ultimately working their mines if it is shown that by such means it can be done without injury to the plaintiff.

PLAINTIFF ENTITLED TO RELIEF.
Whether a dam can be constructed to stand the pressure to which it will necessarily be subjected under these circumstances, and whether it will be of any material use in preventing the flow of the debris and the filling of the river banks, are questions in which I am not fully versed. But from the evidence in the case, and my observations of the premises, I am strongly impressed with the belief, that sufficient of the debris would still pass over the dam in suspension with the water to maintain and even increase the present fill of the river.

Besides, it is a very serious question in my mind whether any person or company ought to be required to submit to the continuous peril of living under or below such a dam as this must necessarily be, if it is made high enough to impound less coarse material; and this merely for the convenience of another person or persons in the pursuit of his or their private business. It may be likened, in part, to the direct pathway of an impending avalanche.

I think the plaintiff is entitled to the relief asked, and concur in the decree ordered.

A Noble Work.

EDITORS PRESS:—I have written the inclosed article for the purpose of making known to your readers the bed-rock principles which underlie the action of the Boys and Girls Aid Society. We wish them to be completely understood by the whole people of the State. Your paper goes among the best industrial classes. They are the very men in whose families boys should be placed.—J. C. KEMP, 228 Ellis street, San Francisco, Cal.

Juvenile Reform.

The Boys and Girls Aid Society, whose exceedingly limited and unpretending home is located at 68 Clementina street, San Francisco, has in the most thorough manner solved the great question, How shall we save to good citizenship our orphan, neglected and wayward children? And being deeply impressed with the fact that this is the most vital issue of the present time, and that the whole people of the State should be made fully acquainted with the plan of this admirable organization, we propose in the present article to give a clear and concise explanation of its method, which has proved the most pronounced and eminent reformatory success of the West, its grand work during the past twenty months having no parallel, either in this or any other country. First of all it bases its action on the great fundamental fact that the well ordered home and family constitute the distinguishing mark between civilization on the one hand and barbarism on the other; and that to this source and this alone must we look for all youthful reformation. It is opposed, first and last, to the wretched, imbecile, institutional idea, which during the past forty years has cost the people of America millions of dollars, and resulted in a harvest of criminals so large that the combined resources of every prison in the land stretched to the utmost tension is not adequate to contain them. Reformatory and so called industrial schools have had their day, and a most terrible and fearfully expensive one it has been, intelligent people everywhere having become fully alive to the fact that such places are, in most cases, nothing more nor less than dens of iniquity, nurseries of crime, and hotheds of the most loathsome and revolting practices, in which children are practically educated, to finally gravitate, first to the jail or House of Correction, next the State prison, and last of all, in

many cases, to an ignominious end upon the gallows.

The Boys and Girls Aid Society, whose method like everything else in nature that is truly useful, is pre-eminently simple, has accomplished results greater and less expensive than those of any other reformatory organization that ever existed, every detail having been brought right down to the most economic basis. To explain more fully, it costs the society to take a boy or girl, feed, clothe and discipline either, and finally place him or her in a well ordered home, then to remain (still under the society's oversight) until of age, then to go forth fitted to assume the duties of life, the comparatively insignificant sum of seven dollars and fifty cents. These are the exact figures, as shown by the records of the society kept during the past twenty (20) months. The expense for food has been so low, that the officers of the society have actually felt a great reluctance to state the amount, which is only eight cents per capita, per day, and which also includes both fuel and light, the children too being better fed than those of any institution we know of; and this the result of bed-rock management—of the employment of no unnecessary help whatever. And in this connection we will state that a Superintendent Assistant and Matron constitute the whole paid force, these three persons performing every duty, aided only by the assistances of such boys and girls as can be made available, there being on an average sixty at its home. Let this reader take the record of reformatory institutions in general, and see what this amount per capita has been. It has cost the State of California about seven hundred and fifty dollars to educate and qualify for the business of robbery, murder and arson, the average of its well trained graduates during the past twenty years, the truth of which assertion can be seen at a glance by reference to its State and Municipal reports. Seven dollars and fifty cents to place a boy or girl in a good home, there to be schooled and brought up for the duties of life by the true method ordained by the Supremes Being, and seven hundred and fifty dollars to make a red handed criminal out of either by the accursed system, acts and tricks, invented and presided over by Satan. Is it not time that the fathers and mothers of the children of this generation looked this most vital matter squarely in the face, and will not, and should not every charitably disposed man and woman in this fair land, in our own beautiful California, come at once to the rescue and help with money, material, word and deed, this noble organization, that during this short period of twenty months has rescued from the very jaws of utter ruin, seven hundred of our boys and girls, and placed them in happy, well regulated homes, where, as the records show, there are but two of this number, placed outside of San Francisco, that are not doing well, that are not fairly on the high road to true sovereign independence.

The society owns a lot on Clementina street, San Francisco, 25x80 feet in size, and their home (a plain wooden one) covers the entire area. In this building the boys and girls are kept just long enough to determine each one's individual characteristics, and then quickly as possible sent away to the most appropriate home that can be found. This process is constantly going on, the building being simply a depot, and not an institution in any sense of the word. As we said before, it needs money at all times. Its quarters are entirely too small, and far more commodious ones are needed, so that it can be enabled to extend its operations, and provide ten children with homes where it now provides but one. It receives no aid whatever from state, county or municipality, except through the few boys and girls occasionally sent to it in conformity with Section 1338 of the Penal Code, but depends wholly upon charitable contributions for the means to meet its obligations.

One of its most pressing wants is a good, reliable, big-hearted Corresponding Member in each town and city in the State, who will act in such capacity without remuneration except the true, pure satisfaction such a noble position should afford and the unqualified respect it would certainly command. Such an one, furnishing all necessary information to those in his or her district who desired to adopt, indenture or employ a boy or girl, and also to act as a sort of consul for both parties, seeing that each lived strictly up to his portion of the contract.

Remarkable Artesian Well in "San Joaquin County.

EDITORS PRESS:—On the farm of Cutler Salmon, between Latrop and Stockton, on the French Camp road, there is an artesian well that deserves a detailed description. It is in reality a double well; the outer casing, seven inches in diameter, is sunk to a depth of 844 feet; inside of this there is another three and three-fourths inches in diameter, sunk to a depth of 1,250 feet; the former throws a jet of water to the height of 16 feet, and the latter 22 feet 8 inches. The flow is 300 gallons per minute, or 432,000 gallons every 24 hours, and the temperature of the water is 80 degrees Fahrenheit. The water from the larger well is of excellent quality, and is used for domestic purposes, the owner claiming considerable medicinal virtues for it, especially in trouble with

the kidneys and urinary organs, having himself been entirely cured of some very distressing symptoms by the use of this water. The water from the smaller boring is not so good, and is used only for irrigation. From these wells there is an extraordinary issue of gas, which the owner has utilized by an ingenious contrivance. He has placed a galvanized cylinder over the mouth of the well, which serves as a gasometer or tank, and catches part of the gas as it bubbles up through the water, which is in a constant state of effervescence till it has discharged the gas and run out of the reservoir into the ditch that is used for the purpose of conducting it over the land. Pipes are laid on from this gasometer to the house, about 100 feet distant, which is lighted and heated by the flame from this gas. In the kitchen, an ordinary cooking stove has been converted into a gas stove by laying 2-inch pipe on the fire basket, connected with an outside pipe just like the fire-back of a common stove, and all the cooking is done there with astonishing cleanliness. In the sitting-rooms, common sheet-iron stoves are converted into gas stoves in the same way, and besides the economy and cleanliness, the temperature of a room can be regulated by simply turning a stop cork. As this gas appears to be inexhaustible, no attempt was made to economize in its use for illuminating purposes; and when turned on full, two burners thoroughly lighted every part of a room 17x13, so that one could read comfortably at the furthest corner. When less force was given the flames burned blue and lost some of its illuminating power; this defect, however, might be remedied by using a particular kind of burner, with finer perforations than the ones in use. The gasometer is only 3 feet in diameter and the reservoir 12, so that much of the gas escapes, and it is impossible, from the simple means used to collect it, to calculate how much gas rises with the water. At the margin of the reservoir, a lighted match held to the bubbles ignites the gas that escapes from them as they burst. This well has been in operation since it was finished in August, 1883, and there has never been any diminution in the supply of either gas or water.

The cost of sinking this well, including the frame building over it, the gas pipes and fixtures, plumbing, etc., was entirely covered by the sum of \$3,600.

Should time demonstrate that the supply of gas is permanent, it would be easy to run it into Stockton and light that city much cheaper than could be done by any other method, and at the same time be of immense value to its fortunate possessor.

CHARLES F. GOMPERTZ.

Modesto, Cal., Jan. 14.

In Twenty Years.

Among the congratulatory notes which we have received on the completion of our first score of years as a firm, is the following from an old Californian, who, though distant, has still at heart the interest and progress of his old friends, and of a State in whose advancement he rejoices:

Messrs. Dewey & Co.—Gentlemen: As one among your host of friends, allow me to congratulate you upon recently passing unitedly time's score as a business firm, also the journalistic score far in advance of all rivals and competitors on the Pacific coast, entering the race since the 1st of December, 1863.

Twenty years in this earth's chronology is an infinitesimal fraction of time. With man it marks a generation. History records no such complete and wonderful changes—national, political or social—occurring as within the last score. The legalized con-sorting of freedom and slavery no longer exists in these United States. Years of war and the blood of a host of martyrs was required to verify as truth what had existed only in theory. Japan, from time immemorial shut up and excluded from the world, now ranks among the most progressive of people. Ancestral China, with consecutive historical records ante-dating time as previously computed, proudly exclusive, bigotedly conservative, anxiously seeks admission into the convulse of nations. Geographical research has lifted the veil from a vast continent, with its millions of idolatrous inhabitants. A boundless field is opened to the philanthropist, the missionary, the trader and the agriculturist. The long sought for sources of that ancient, yet mysterious river, the Nile, have been determined, after baffling adventurous travelers of many nations for generations. The vexed problem of an Arctic passage has been solved. Science has subjugated to man's uses the most erratic, subtle and powerful of nature's forces—electricity, which lights, speaks, writes and labors for him, with possibilities of development beyond conception. From earth's deeply buried resources fountains of oil have poured forth, lubricating the commercial wheels of this and other lands, added millions to our wealth, a priceless benefit to mankind.

Space forbids more than this tracing a few of the most prominent of the many objects, dating within the past twenty years. With the complacency of the season, coupled with a wish that you may enjoy many returns, with increased abilities of appreciation,

G. C. PEARSON.

Danville, Ill., Jan. 1, 1884.

UTAH'S MINERAL PRODUCTION.

Wells Fargo & Co's Statement for the Year 1883.

Olive Oil Manufacture.

Elwood Cooper writes to the Santa Barbara Press, as follows:

The berries are dried before crushing, as it is necessary to evaporate a portion of the water. If, however they are left out on the tree until shriveled, which is proof that necessary evaporation has already taken place, no drying is needed after picking. This late picking is not best, as mentioned in a previous article. If dried by the sun, it requires about fourteen days. This plan cannot be depended upon, excepting years when fruit is early ripe, and we have continuous sunlight, with moderately warm weather. By artificial heat ranging from 110° to 130°, the drying can be done in less than forty-eight hours. The crushing and pressing should follow without delay—that is, the fruit taken from the drier in the morning should be crushed and pressed the same day. Long intervals or delays in the process from picking the fruit to expressing the oil tends to rancidity. To make perfect oil requires a perfect system in the whole management. The capacity of the press, the crusher, the drier, and the number of pickers should correspond or be about equal; all fruit picked during the day should be in at night, cleaned the following morning, and go into the drier immediately after the previous day's drying is taken out. The heat or temperature of the drier ought to be so graded as to complete the work in forty-eight hours, and it is better that it should be under 130° rather than above. Economy will necessitate in the business a system in the different branches of the process admitting of no delays from the beginning to the end.

My drier has capacity of 500 square feet of surface, and will contain at one time 2000 pounds of olives, equal to five pickers of 400 pounds each per day and as much as the crusher and press I am now using can work.

The almost universal method of crushing the berries is by a heavy stone, similar to a mill stone, which is rolled round on the edge in a deep circular groove or trough, and by its weight does the crushing. A beam passing through the eye of the stone, and working on a journal in the center of the circle with a horse attached to the outer end of the beam, is the simplest way to do the work, and the plan that I have adopted. The circumference of the trough depends somewhat on the size of the stone. The one I am using is four feet high, six inches thick, and the diameter of the trough in which it works, six feet; the length of the beam fifteen feet. This crusher is amply sufficient for an orchard of one thousand trees, but too small for my purpose. It cost about \$50.

A stone five feet in diameter and two feet thick would crush in eight hours a sufficient

quantity of berries to make 100 gallons of oil, and by working it night and day, the crop of ten thousand trees. It would be better, however, to have two stones half the thickness of the above, one following the other in the same groove. The horse should work on the outside of the building containing the crusher.

To make 100 gallons of oil each day would require two good presses. The one best adapted for the purpose as far as I have seen, is that used for making oleomargarine. Such presses could with very little expense be worked by the horse power used for crushing the berries, so that one man could do all the crushing and pressing.

The press I am using is an old-fashioned wooden beam press, such as used in the New England and Middle States for making cider. The beam is 26 feet long, and with a heavy box filled with rock suspended at the extreme end, the power can be increased to 150 tons. The press with the differential pulleys cost about \$150. Such a press cannot be improved upon for expressing the oil, but the additional labor and the time lost in changing is so much greater than what would be required for the oleomargarine invention, that the latter would facilitate the work, and be cheaper in the end, besides taking up so much less room.

The crushed olives are put in the press in cheeses about three feet square, and three inches thick, with wooden slats between each cheese. Ten or more cheeses can be put in at each pressing. I use coarse linen cloth to contain the crushed olives.

The fluid that is expressed is put in large tanks, and left for sixty to ninety days, when the oil will separate, and being lighter will rise to the top, where it can be drawn off. The pomace after the first pressing is re-crushed, and by pouring hot water over it, a second quality of oil is expressed. The refuse can be used either for fuel, for feed for pigs, or for making still a third quality of oil; if for the latter, it is thrown in vats, holling water poured over it, and left to ferment, when the oil still remaining will be liberated and rise to the top.

ELLWOOD COOPER.

MAHOGANY.—The manufacture of mahogany furniture has, perhaps, increased four-fold within the last two years. This increase comes from the demand for high-priced furniture, as well as from the deterioration and scarcity of black walnut. This beautiful wood is now largely being made use of for interior finish—many of the finer houses, banks, insurance offices, etc., being finished with it. Its use is entering rapidly into the construction of rail way carriages—a source of demand uniformly good for hard woods. The chief sources of mahogany are Mexico and the West Indies, and the United States takes 25 to 30 per cent of the whole exports.

About Obtaining Patents.

Patents are Virtually Contracts

Between inventors and the public. The consideration flowing from both parties to the contract is expressly fixed by statute. The Government requires the following consideration in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in a printed publication prior to the date of his invention. Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees that the inventor shall have the exclusive right to make, use and sell the thing invented for the term of seventeen years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented by another. This requires an exhaustive search among all the patents in the class to which the invention relates. This question can often be answered gratuitously by us, immediately on receiving full information of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class, scientific and industrial journals, during the past 20 years and over. When the question of priority of invention is not so readily to be determined, it is generally best to make what is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing compilations of special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1860.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of \$5 for the examination, a verbal or written report showing definitely where his invention has been anticipated, thereby saving him further expense and perhaps much time, useless delay, anxiety, etc.

To avoid all unnecessary delay, however, in securing patents at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps to be taken.] When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of \$20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretence of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give a case up as long as there is a chance to obtain a patent. The Agency charge is from \$25 to \$30, or sometimes more, if the invention is intricate or complicated, or requires much labor. Drawings cost from \$5 upward, according to their number and the time employed, and, if a model is sent, the express charges upon this and the papers must be added. The total cost, in addition to Government fees, rarely exceeds \$40, and for this we do all we can without appealing the case.

When the invention consists of a new article of manufacture, or a new composition, samples of the separate ingredients sufficient to make the experiment and also of the manufactured article itself, must be furnished.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are considered more satisfactory to the Patent Office than the old and more cumbersome system of storing up an immense bulk of almost numberless models.

Drawings or sketches, sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it for us.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents of this character are brought into court, the uncertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts intended to be covered by the patentee. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken that the invention is fully and clearly shown by different views, so that the improvement will be readily understood by the examiners in the Patent Office, and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and in due time is carefully examined to test the novelty of the in-

vention. If the examiner fails to find anything that anticipates the invention, a patent is immediately allowed, provided the specification and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims in the application, a letter of rejection is sent to the attorney in charge of the case; and, if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected on patents which do not anticipate the spirit or wording of the claims, proper steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patents shall be complete, an oral argument is generally supplemented by a manuscript brief, that others, in examining the files at any future time, may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to a patent.

In addition to our own personal attention to the interest of our clients here, we have, for over 12 years past, had constantly in association with us in Washington, one of the soundest legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office, and has attained success in a most marked degree.

Perfect Claims.

The value and force of a patent are dependent on its claims. A patent may disclose to the public the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can flood the market with improvements, differing from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the Patent Law. Hence it is that the greatest care skill and perseverance are required, first, in properly drafting the claims in the first instance, and second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The Examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their sworn duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that Examiners are sometimes in error as to just what scope should be accorded an invention. Although the Examiners act under honest convictions in cases where they refuse an inventor his just rights, yet it is the duty of the attorney to maintain the claims of his client, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & Co. (continuously editors and publishers of the MINING AND SCIENTIFIC PRESS, nearly from its early commencement in 1860) offer comparatively far better facilities to the local inventors of the Pacific States and Territories than are possessed by any other agents in America. Members of the firm give personal attention to the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured more U. S. and foreign patents in the past 20 years (with very few exceptions) than any other firm still existing. Their practice has been so successful and long continued, that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

The extensive business combination and experience of this firm, is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice, and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time, Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of this coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is, that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, and which is adjudged to be novel, and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; con-
centrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No.
220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we
Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concen-
tration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as
soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other
machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

January 3, 1884.

MORRIS

Improved Amalgamator AND SETTLER.

Any parties having ore or precious metals in their tail
ings can procure my

Apparatus and Improved Method of Con-
centrating Ore and Tailings.

I will put my new and improved method in force on a
percentage or sell it after trial.

THE ROLLER ORE FEEDER.

[Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use.
It has fewer parts, requires less power, is simpler in
adjustment than any other. Feeds coarse ore or soft
clay alike uniformly, under one or all the stamps in a
battery, as required.
In the Bunker Hill Mill it has run continuously for two
years, never having been out of order or costing a dollar
for repairs.

Golden State and Miners' Iron Works,
Sole Manufacturers,

237 First Street, SAN FRANCISCO, CAL.

Carson and Colorado Railroad.

(NARROW-GAUGE.)

The Company announce the completion of its line March
1, 1884, to CANDELARIA, Coahuila Mining District, Mex-
ico, 135 miles from Mound House (junction with
Virginia and Truckee Railroad).

STAGE CONNECTIONS,

At Hawthorne with U. S. Stage Company's daily coaches
for Aurora (26 m.); Bodie (37 m.); Lundy and Elkoport.
At Luning (125 miles from Mound House) with C. & N.
Stage Co.'s tri-weekly stages (leaving Tuesday, Thurs-
day and Saturday mornings) for Grantsville, Belmont and
Tulia.

At Belleville (150 miles from Mound House) with Belleville
and Independence Stage Co.'s stages for Leno (40 m.),
Bishop Creek, Big Pine and Independence.

At Candelaria, with U. S. Stage Co.'s stages for Col-
hins (6 m.), Silver Peak, Montezuma, Alida Valley and
Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento,
Reno, Carson and Virginia R. R. Ticket offices.

This is the direct and natural route for Passengers and
Freight to points in Southern Nevada, Mono and Inyo
counties, California. The line, laid with steel rails and red
wood ties and equipped with new and first-class rolling stock,
is penetrating rich and most promising Mining Districts
which are now attracting deserved attention throughout the
country.

For information on through tickets apply to

H. M. YERINGTON, D. A. BENDER,

Gen'l Supt. Gen'l Freight & Pass. Agt.,

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Abe Co., Black also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 6,000 feet Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful Rivets Hand Driven.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Duc's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr. Brooklyn, N. Y.

SELBY SMELTING and LEAD CO.,

416 Montgomery St., San Francisco.

Gold and Silver Refinery And Assay Office.

HIGHEST PRICES PAID FOR Gold, Silver and Lead Ores and Sulphurets.

Manufacturers of Bluestone.

ALSO, LEAD PIPE, SHEET LEAD, SHOT, ETC.

This Company has the best facilities on the Coast for working

GOLD, SILVER and LEAD IN THEIR VARIOUS FORMS.

PRENTISS SELBY, - - Superintendent

The California

Perforating Green Co.

All kinds of Quartz Screens, slot or round holes; zinc, copper and brass for flour and other mills. BOWK & WAGNER 123 and 125 Beale St., S. F.

JOHN L. BOONE, Attorney and Counsellor-at-Law,

Rooms 7, 8 and 9,

320 California Street, San Francisco.

(Over Wells, Fargo & Co.'s Bank.)

Special Attention Paid to Patent Law.

N. B.—Mr. J. L. Boone has been connected with the Patent business for over 15 years, and devotes himself specially to Patent litigation.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tanned Manila Rope, Hay Rope, Whale Line, etc., etc.

TUBBS & CO.,

611 and 613 Front St., San Francisco.

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Glossary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commissions Codification, and gives many an improved form. Price—Full law binding, extra paper, \$3.00.

For Sale by DEWEY & CO., San Francisco.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

"TRIUMPH" ORE CONCENTRATORS.

The Best Ore Concentrator in the Market.

In presenting the above Improved Form of an Ore Concentrating Device to the mining public, we feel confident in our ability to supply the demand for a successful, practical-working machine.

One of them can be seen in operation, and we invite the attention of those interested to a critical examination of its merits, and will furnish prices at

JOSHUA HENDY MACHINE WORKS,

Nos. 49 and 51 Fremont St.,

San Francisco, Cal.

GOLD QUARTZ and PLACER MINERS'

Silver Plated

AMALGAMATING PLATES,

For Saving Gold.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 2,000 ORDERS FILLED.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought or gold separated for low percentage of result.

 - 291,302.—LOCKING LATCH—E. Nyswonger, Hanford, Cal.
 - 291,434.—KEY FASTENER—E. W. Wagner, Cherokee, Cal.
 - 291,250.—PUMP—A. W. White, San Jose, Cal.
 - 291,254.—WINDOW BLIND—Jos. Williams, San Jose, Cal.
 - 291,121.—FORCE PUMP—H. M. Wyeth, Salt Lake, U. T.
 - 10,832.—TRADE MARK—Siebe Bros. and Plagemann, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Mining Share Market.

The market for mining shares remains in about the same state as for some time past, there having been no bonanzas of late to give it any strength. If there is any change at all, however, it has been a little for the better, perhaps. The long interval which has elapsed since a rich strike was made on the Comstock has discouraged many, but the miners up there are still hard at work in a hopeful manner.

The season of inactivity is about over, and the time is drawing near when something decisive must be done in one direction or another. This is particularly the case at the north end, south end and middle mines.

At the north end the Sierra Nevada folks are again going ahead with their northeast drift, and find that the quartz in the face is widening and improving. As this drift advances it will cut the rich ore streaks encountered in the joint Union Consolidated cross-cut, which was run out east a distance of twenty-eight feet. The last streak cut in this drift was eight inches thick, and rich in gold. In about five weeks the north and south drifts in the Union Con. will be connected, forming an air gallery which will constitute a base of operations for all the north end mines. Then real square prospecting may be done.

At Gold Hill the Yellow Jacket and other companies are taking out as much ore as the mills on the Carson river can handle, and in addition all are doing more or less work in the way of prospecting. Once there is a good stage of water in the river, the Gold Hill mining companies will enter upon a prosperous season.

At the middle mines all is now going on very satisfactorily. The new hydraulic pump is all that could be desired, and all operations may now proceed without the least fear of being flooded out by water. The combination shaft will be put down to the 2800 level as speedily as possible, and from that point a drift will be run west to connect with the Hale & Norcross.

If you want a lubricant that will run any thing cool write CHARLES J. WOODBURY, GENERAL MANAGER LUBRICATING DEPARTMENT CONTINENTAL OIL AND TRANS. CO., for "Lubricoil." It is the best compound grease in the market. Shipped in 5, 10 and 25-pound cans, half barrels and barrels. Warranted to give satisfaction. Observe the numbers: No. 3 is soft for outside work; No. 5 is medium soft; No. 4 is medium hard; No. 5 is very hard, where unusual lubrication is demanded. Send for Catalogue of Lubricating Oils.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

MINING, QUARTZ, AND SAWMILL MACHINERY.

AUTOMATIC ORE-FEEDERS, HENDY AND TRIUMPH CONCENTRATORS.

— AGENTS FOR THE SALE OF —

Baker Rotary Pressure Blowers Akron (Ohio) Hot-Polished Shafting.

Wilbraham Rotary Piston Pumps, Blaisdell & Co.'s Machinists' Tools.

F. A. HUNTINGTON, SAW, SHINGLE, AND QUARTZ MILL MACHINERY.

We Call Attention to the Following Testimonials as to the Capacity and Durability of the Centrifugal Roller Quartz Mill:

SAN FRANCISCO, Dec. 27, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—The four-foot Centrifugal Roller Mill, bought of you in August, 1882, for the Whidden Gold Mining Company, of Shingle Springs, has given entire satisfaction, both on our own and on custom work, saving from 85 to 90 per cent. of the gold in the mill. In conclusion I will say that we are so well pleased with it that Mr. Whidden and myself are putting one of the same size on the Tohongo gold mine, near Ravenna, in Los Angeles county.

Yours truly, P. YEASEY,
34 California St., S. F.

FINE GOLD GULCH, Nov. 10, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—In reply to your inquiry concerning the working of your Centrifugal Roller Quartz Mill, I am pleased to say that I run one of them for seven months, doing custom work on different varieties of rock, and that the mill gave satisfaction in every respect, and did all that you claim for it.

Yours truly, BYRON JENNINGS.

GARIBALDI MINE, Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to yours of the 10th inst. I take pleasure in assuring you that your Centrifugal Roller Quartz Mill gives entire satisfaction, and I can heartily recommend it to mining men who want a cheap and efficient crusher.

Yours truly, E. I. PARSONS, Supt.

32 WASHINGTON AVENUE,
SAN FRANCISCO, Dec. 29, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: Having run one of your Centrifugal Roller Quartz Mills on sample lots of rock from more than twenty different mines, I must say that in every instance it has given the best of satisfaction in every particular; and I recognize its superiority over any other mill manufactured. Very truly yours,

D. O. MOWRY.

CENTRIFUGAL ROLLER QUARTZ MILL.

The work done by the Centrifugal Roller Quartz Mill, during the past two years, on various mines and different kinds of rock, PROVE ALL THAT IS CLAIMED FOR IT.

After running one of these mills on the Whidden mine, in El Dorado County, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop-stamp mill.

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

CAPACITY AND DURABILITY GUARANTEED.

F. A. HUNTINGTON, 45 Fremont St., San Francisco.

Where a Machine can be seen in Operation.

Sample Lots of Ore Worked.

SONORA, CAL., Dec. 1, 1883.

F. A. Huntington Esq., San Francisco, Cal.—
DEAR SIR—In reply to yours of recent date, inquiring about the Centrifugal Mill which I bought of you, I will say that I have run the mill four months on hard rock; and I take pleasure in adding that the mill has in every way given the best of satisfaction.

Yours truly, J. H. NEALE

GARIBALDI MINE,
Calaveras Co., Cal., Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In answer to your inquiry concerning the working of the five feet Centrifugal Mill, bought of you for the Garibaldi Mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

Very truly yours, O. B. SMITH.

F. A. Huntington Esq., San Francisco, Cal.—
DEAR SIR—Your Centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Co. property at Shingle Springs, El Dorado Co., Cal., about four months, and it has done good and satisfactory work, a greater proportion of gold remaining in the mill than in the stamp battery.

FRED JONES, Supt.

HILBRETH RANCH, Fresno Co., Cal.,
January 11, 1884.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: In regard to your mill (Centrifugal Roller), I have crushed about 500 tons of rock in the mill, and am glad to say that it has given entire satisfaction, and can recommend it to the public as the most expeditious and least expensive method for crushing and milling ore that I have ever seen. Truly yours

THOS. HILBRETH.

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, or sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Dary Valve Motion, superior to any other Pump.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE ever invented for the service of Prospectors and others requiring the use of a Horse Power; possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower without interfering with a hoisting apparatus.

It is made entirely of Iron; no piece weighs over 250 pounds. At the ordinary speed of a horse a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope. The cost of erection is slight, as two men in half a day can easily put it in place ready for work.

While this power is more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. **SEND FOR CIRCULAR.** Address

SAN FRANCISCO, SATURDAY, JANUARY 26, 1884.

VOLUME XLVIII
Number 4.

New Concentrator and Amalgamator.

George R. Evans, of this city, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency a new form of concentrator and amalgamator, the interest in which has been assigned to J. P. Couch and Wm. T. Oneale. The appliance consists of a sluice box or trough having its bottom formed into peculiar curves or rilles, over which is fitted an amalgamated metallic surface. The bottom of the sluice may be of wood or metal. The upper surface is formed in a series of flat and curved surfaces, on which the amalgamated plate (corresponding in form) is placed. The first portion of each section is made flat, and the sluice is set at such an angle that while it declines from the receiving to the discharge end these surfaces will be nearly or quite level.

Continuing from the edge of the level space, the surface makes a concave sweep so as to form a long, shallow curve, and from the termination of this the surface rises into a convex curve, which extends down and terminates abruptly and nearly vertically upon the next plane surface. In this manner a succession of these surfaces is formed, which continue to the end of the sluice. As stated, the surface described is covered with amalgamation plates of corresponding form.

The pulp, tailings, or other material being admitted to the sluice with a sufficient amount of water, falls upon the first plane surface, where the gold and heavier particles sink to the bottom, and the flow is retarded because the surface is level. From this the flow increases through the concave portion, and this forms a sort of rille in which there is a forward current upon the top and an eddy or return current at the bottom, which throws the fine gold back upon the first part of the curve, where the greater portion will be found amalgamated.

The coarser and heavier portions will be detained and amalgamated in the lower part of the curve, while the lighter portions will flow over the convex portion and fall nearly vertically upon the succeeding plane surface, this latter action projecting the heavier particles at once to the bottom and in contact with the amalgamated surface. This action is then continued through as many series as the length of the sluice will admit, and the inventor claims results in a very perfect concentration and amalgamation.

DESERTED DITCHES.—An effect of the recent debris decision will be, as we stated at the time, a general desertion of the ditches, dams, etc., in the mining regions. A ditch tender of the North Bloomfield Co. informs a Nevada *Transcript* reporter that "on Sunday the company ordered all the men off the line, gave instructions to have the waste-gates thrown wide open, and will this winter let their 157 miles of canals and flumes, which were constructed at a cost of \$708,841, take care of themselves. Mr. Bates says that the Milton Company (having 80 miles costing \$391,179) and the Eureka Lake Company (with 163 miles costing \$723,342) have likewise abandoned their ditch properties, and the army of white men heretofore required to keep them in repair are now without an occupation. The principal damage that will result to property will be from snow slides that may sweep some of the flumes away from their elevated perches on the precipitous mountain sides.

The State Mining Bureau.

This institution, though crippled from want of means, has done much during the year past towards promoting the several objects for which it was created. A large number of geological and mineralogical specimens have been collected and properly cared for, the more important having been classified, labeled, and where there were facilities to that end, placed in mounted glass cases. The additions to the museum have been numerous, the library has been somewhat enlarged, and many minerals have been examined by the State Mineralogist, and information concerning them given to parties seeking the same. An immense number of people, many of them strangers from abroad, have visited the rooms of the Bureau, evincing the deep interest taken by the public in all

A Railroad Inspection Car.

The illustration on this page shows a new form of three wheeled inspection car for railroad use. It is propelled by one person, and is so arranged that another person may be carried. The division superintendent or road-master being thus able to frequently and closely inspect the road with little trouble. In this way, by taking a section-hand to run the velocipede, he can personally visit a large portion of the section under his charge in a single day, and have needed repairs made immediately.

The car is propelled by a rowing motion, and auxiliary foot-power. The frame, wheels and arm are made of white ash, the frame being firmly held together by bolts. The arm or outrigger is stiffened by an iron brace. The tires are cast iron, the axles and crank shaft are

A NEW INSPECTION CAR FOR RAILROAD USE.

that pertains to our mining industries, mineral resources and the geology of the State. A good many young men, residing both in the city and the interior counties, have been frequenters of the Bureau of late, coming to study and familiarize themselves with the mineral specimens, with a view to searching after them in the field; what is seen and handled being so much more readily recognized and better remembered than what is merely described in books.

This institution, if sustained and properly fostered, will become not only a promoter of science, but a great educator of the rising generation.

In view of the approaching World's Fair, which it is proposed to hold in San Francisco, it becomes to Californians a matter of consequence that the life at least be kept in this institution until that event occurs, since it would be sad indeed if to the thousands who may then be expected to congregate here we had only the remains of the late deceased to be presented.

iron, and the crank and stirrups of malleable iron. The arm or outrigger is adjustable and can be removed at will. The car weighs about 140 pounds, and is made with either a 17 or 20 inch drive; geared three or four and a half times as may be deemed expedient. It is stated that there are some 4,000 of these cars in use, both in this country and in Europe. H. P. Gregory & Co., Nos. 2 and 4 California street, in this city are agents for this coast, and have put several of them in use in the State. Mr. John Vance, who is using one of them on a railroad in the lumbering region near Eureka, says it exceeds his expectation and is exceedingly useful. Several forms are made, one for a single individual; one to carry two, as we have shown in the engraving; and one intended for two men to propel and carry tools, etc. The latter is useful for the repairers of a telegraph line along a railroad, and for ample repairs on the road itself. It supplants in many instances the cumbersome hand-car ordinarily in use.

Notes Upon the Rings of Saturn.

At the last meeting of the California Academy of Sciences (January 21st) Professor Davidson reported upon some special investigations which he had been making upon the planets, and called attention particularly to the division of the outer ring of Saturn and the phases of the dusky ring.

The outer ring is not divided into two rings of equal breadth. On the preceding part of the ring the Encke division is nearer the outer circumference, but on the following part of the ring the Encke division appears farther from the outer circumference.

The preceding exhibition is the true one. In the case of the following he showed that the shadow of the elevated outer circumference of the B, or main ring, projected beyond the Cassini division, and there by decreased the visible breadth of the inner breadth of the outer or A ring. On the 17th of January the atmosphere was sufficiently steady to admit a comparison of the apparent width of the dark Cassini ring at the preceding and following parts of the ring system, and the dark ring appeared broader at the following part where the shadow would be cast.

Upon a great many nights the preceding part of the dusky ring appeared brighter than the following part. Some very few times this has appeared, but whenever the atmosphere has been fairly steady the first condition seemed to be normal. The question naturally arose whether the rotation of the ring could be discovered from watching this phenomenon; but no prolonged equable condition of the atmosphere was experienced. Again, it seemed that the direction of the unsteadiness of the atmosphere might influence the judgment. But he seems to think that a reasonable solution is found in the preceding part of the dusky ring, now receiving more light than the following part, because the surface of the planet would reflect its light more upon the preceding than upon the following, on account of the preceding side of the planet being more directly faced towards the sun.

Another item of interest with regard to the dusky ring, is its appearance when projected upon the body of the planet. It does not seem to fade away from its junction with the ring B, to its inner circumference, but the inner circumference appears more as a darker line. Of course there is the probability that there may be a dark line on the body of the planet in line with the inner circumference of the dusky ring, and thus the above appearance would not then be simply the effect of an increase of density of the inner ring nearest the planet.

These are matters for larger telescopes and he hopes they may be examined.

A curious accident occurred last week at the Sheep Ranch mine, in Calaveras county. Mr. Javaux was ascending the shaft on the tub, when a strand of the wire rope broke after the tub had made an ascension about 200 feet from the bottom. The strand of rope after it had been broken began to unwind with a lightning velocity, and went whirling down the shaft with a dangerous whirl towards the human freight on the tub. Mr. Javaux, realizing his perilous situation, jumped from the tub, and by chance caught on a slippery timber. He was obliged to stay there until assistance came down the shaft.

CORRESPONDENCE.

Tuscarora Mines.

[From our Traveling Correspondent.]

EDITORS PRESS: Tuscarora Mines, Elko County, Nevada, by many on the outside have been considered to be practically worked out and dead, with no hope of a day of resurrection for this part of Nevada. They recollect of Tuscarora's prosperous days, her massive specimens of solid silver nuggets, and her large bunches of wire silver moss, clinging to beautiful crystallized specimens that far discounted any of the finest specimens that the Comstock ever produced in her best days. The Comstock has several times been pronounced dead, and long before she had reached half her productive strength or half her present depth very prudent ones pronounced her solemn obituary, and the world was assured that the day of profitable working was past with the Comstock mines.

Tuscarora, like very smart children, they "knew was destined to an early death." The history of mines is constantly repeating itself. Whenever, for one reason or another, either parsimony, poverty, or an entire lack of mining skill, or for any purpose of stock manipulations, the development work is allowed to stop while the rich ores in sight are being extracted, we are almost sure to hear of a worked-out mine, and often a suddenly abandoned camp.

The Navajo.

Belle Isle, North Belle Isle, Independence and the P. and P. mines are all under the superintendence of Mr. W. C. Price, who entered on his arduous duties in 1882 under many discouraging features—much repairing and improving to be done about mill and mine machineries. But the more important task was the driving of prospect work in the mines to open up the ore chambers and stoppings that would produce the regular shipments of bullion as in the prosperous days of old. By sinking and crosscutting in different directions, and by very close and careful study of the formations and relations of the stratifications, the various spur dips and breaks of the leads were traced, and good bodies of rich ores rapidly brought to the surface, and still other rich bodies of stoppings opened ready for removal.

My journeyings under ground in company with the underground foreman, each with lighted candle in hand, wandering through different drifts and levels of the Navajo mine, were interesting. We saw the timbers, large and stout, that had been gradually pressed between the walls of the tunnels until the ends had shivered up for several inches, and additional posts still larger had been added, to support the pressing rock walls. It was quite interesting to know: "Here we found rich ore, and just up there were some pockets of splendid specimen ores." "Here we run this uprise to the tunnel above to improve the ventilation." You can wander around a long time in this mine, and see no pay ore—only see where it has been, and though 60 to 70 men were working there, you see scarcely any of them, for the most of the men will be working between the different levels, stopping out the ledge matter which is there retained until allowed to descend into the tunnel car through the chute door. The Navajo's principal workings are above 450 feet level. The richest ores are on the lowest levels, 450 feet from the surface.

The lowest sinking on this mine, when there last of November, was 680 feet, where they found but a small amount of water. The surface ores were chlorides, changing to sulphurets when coming in contact with the water—and even that called chloride ore carries enough of sulphurets to require furnace treatment for successful working; and this is provided for in a double Howell and White rotary—the first to oxidize the base, and the second, in which the salt is added automatically, the chloridizing of the silver is done very successfully and very cheaply.

From the Superintendent's annual report of August 1883, we learn that the 10-stamp mill ran 300½ days, milled 3,955.35 tons of Navajo ore, 282½ tons of custom ore, making an average crushing of 13½ tons of ore per diem. The average pulp assay of the ore from the Navajo mine was \$199.40 per ton, and was worked to 92-3.5 per cent of the battery assay; custom ore averaged \$332.10 per ton and was worked to 92 per cent. (This, considering the worn condition of the mill, is a very successful working). Shipped bullion on customers' account to the amount of \$64,863.42; on Navajo's account, from Navajo ore, \$730,379.38; from custom ore, \$2,206.58; making a total production in bullion of \$818,898.75, (assay value), from the 21st of July, 1882, to 7th June, 1883.

During the year the main operations of the mines under the charge of Mr. Price have been developments for the future—sinking the main shaft 350 feet through very hard rock, and running various drifts for the development of new stoppings; improving the facilities for power drilling, and for the pumping of the increased waters from the lower levels. To give even a small epitome of the underground works and various plans for success in the most economical and thorough manner would make this too long a communication.

Last summer these dilapidated 10 stamps were sending out from Tuscarora an average of

over \$73,000 per month, and disbursed to stockholders dividends of \$200,000—for this is a dividend, not assessment-paying property.

Mr. Price is highly spoken of by the best business men of the community, who give him much credit as an energetic, skillful, economical and successful Superintendent. No where about the premises did I see any except what appeared to be good, sober, reliable men, and remarkably free from improper language.

The Belle Isle and the North Belle Isle are working through same shaft, with good hoisting works—working about 35 men. The independent also with good works employ about 20 men. These several four companies are San Francisco incorporations, and all under the charge of Mr. Price.

The Grand Prize

And Argenta mines, lying on the opposite side of the town from the Navajo, each hoist through same shaft. The principal owner of these very valuable mines is Mr. (F. W. Grayson, of San Francisco. The ledge is, at the surface, from 4 to 15 feet thick, chloride ore, but at the depth of 180 feet they encounter some water and the ore changes more to sulphurets, and requires roasting to work successfully. Their 20-stamp mill is so situated as to run the car from the shaft direct to the mill, where it is crushed dry and then passed through the Howell-White rotary furnace and then through the usual pan processes.

The mill was started up when I was there, and has since been making some large shipments of bullion, as I have noticed in the *Tuscarora Times Review*, a live sheet of a very neat little mining city of about 1,000 people. Not having the bullion figures at hand I will omit them for the present. They are too large to guess at. The hullion bar, say of \$1,800 value, will have \$80 to \$90 of that value gold. This company met with a very serious loss on the 29th of June last, by the burning of their large hoisting works, which have been but partially replaced. They are able to work only 400 feet levels, instead of going down to their 800 feet level, where they were sinking before the fire. When there they were working 55 men, but expected soon to add 20 to 30 more men. This property has produced many very fine specimens of nugget and wire silver that here and there seem to be injected in the quartz crystal cavities. This property has already made a grand record, and holds in reserve the grander prizes yet to be developed and shipped in bullion. The fuel is being cut off for a few miles distant, but can be obtained yet for a few years before they will be dependent on the railroad for coal which is now being used some little.

There are several other mines in and about Tuscarora partially opened, and that inspire their owners with visions of the bars and bricks, and also with a hope of soon being able to visit friends, and make a home under more sunny skies than they can now realize in their tunnel labors.

The Town of Tuscarora

Was to me a great disappointment. In every respect it was far ahead of all my expectations. It has a pleasant, sunny location on the warm south and easterly slope, looking off on an extensive valley with gentle hills off beyond. The elevation of the town insures about the true thermal—being between the severe frosts of the valley in front and the snowy heights of the mountains in the rear.

The families seemed to be of good social standing and intelligent grade, believing in good schools, and were maintaining an able minister, a large singing school and Sunday School; hotels, restaurants and lodging houses seemed to be made very pleasant for the visitor. They have "the will and way" of treating visitors so that they would like to stay longer. A trip on Mr. Cluggage's stage from Elko—a distance of fifty miles—is over rolling hills and pleasant valleys, giving a good appetite at the half-way house (Wieland's) for a dinner that is noted for the universal praise it receives, and the severe criticism it causes to be heaped on all Chinese efforts as compared with the truly orthodox American woman's family dinner.

Mart Smith, stage agent and express man at Tuscarora, sees well to the comfort of all who are to be seated, and starts them out on time, each feeling that he is having the first choice of seats. A well armed escort is sent along with the hullion shipments.

If Tuscarora could only have the benefits of a near coal mine she would soon develop a very wealthy mining camp. She now has a small foundry and machine shop by Mr. James Dove, serving a great convenience for machinery repairs. There are several large full assortment stores for all the necessities of the town and surrounding country ranches. Game, too, is very abundant; venison plenty.

The great need is for men of capital to employ some of that capital to develop the mines that are owned by poor men, who have not the means to place machinery and do the opening labor. Merchants who must here carry large stocks and advance large amount of freight money to land goods here, cannot advance money to open mines, nor can they sell goods on long credits to the men who wish to open mines, even though they may have the greatest assurance of the merits of the claims.

Elko, the county seat, is thriving as a railroad town and shipping center to various mining camps. Has two newspapers, a daily and a weekly, besides, the daily issues a weekly. The county has able and reliable business men in the various county offices, and is moving on steadily in mining, agricultural and stock develop-

ments, having a bright future before her. Elko has the initiatory startings for a State Mining School now open and a class going on in a course of practical assaying.

The State University has also made its starting here with quite a creditable academic class (both sexes), under the charge of Prof. Farrington, a teacher of considerable successful experience on the Pacific Coast.

The agricultural resources of Elko county are by the cattle men greatly underrated, some say, "and that, too, for a purpose." They prefer plenty of room and free roaming for their herds.

I found Superintendent Charles Crandall, of Elko Consolidated Hoisting Works, Tuscarora, quite busy pushing on the development work very quietly. Had reached depth of 200 feet in the working shaft and made connection with north shaft, 165 feet distant; was expecting to crosscut and expose more mineral; was working only a small force, four men on each shift, but probably by the opening of spring he will be able to make agreeable reports to the San Francisco and New York stockholders, and annoy the stage company with ponderous foot-mashing bricks as ballast. Had I not visited Tuscarora after a small snow storm, I might have done her better justice by visiting some of her mines outside the city limits.

B. W. CROWELL.

A Short History of a Gigantic Quartz Claim.

[Written for the Press.]

Near the town of Washington, Nevada Co., on what is known as Phelps' Hill (a horseshoe shaped mountain), is located one of the most gigantic quartz ledges ever discovered on this coast. The ledge proper is from 40 to 60 feet between walls, but upon first approaching the claim it has more the appearance of an immense quarry of quartz; for the reason that immense boulders have fallen from the croppings, which tower above the ground in some places from 100 to 150 feet. This claim was originally located by Captain Miller, in 1874, who first named it the "Bessie Miller," but afterward changed it to the "Giant," which it bears at the present time. It has been developed by running three tunnels, lower, upper and middle.

The first tunnel started to tap ledge was the lower, and of such dimensions as to enable the ore cars to be drawn by mules. The estimated distance to tap the ledge is from 900 to 1,000 feet, giving about the same number of feet of backs, or ledge overhead.

After driving about 100 feet, Captain Miller, in estimating the expense of running so large a tunnel the great distance necessary to tap the ledge, found it would be so great that he feared he could not raise the required capital; he, therefore, decided to discontinue it for the time being, and start one of the usual dimensions further up the side of the mountain.

Soon after, he began what is known as the Upper Tunnel, estimated to tap the ledge at 200 feet, giving about 75 feet of backs. He had driven about 120 feet, when, in June, 1879, he entered into partnership with a San Francisco capitalist, who agreed to develop the property to the extent of \$20,000, for one-half interest. Before closing the agreement, this capitalist had the rock mill-tested, in order to satisfy himself as to its value. Three tons were broken from the boulders which had fallen from the croppings, and milled in Nevada City, yielding \$18, or \$6 per ton. At the same time a government survey was made by Deputy Surveyor Samuel Bethel for United States patent.

Immediately after entering into partnership the middle tunnel was resolved upon. This tunnel is estimated to tap the ledge at 400 or 500 feet, giving about 400 feet of backs. Their intention in driving this tunnel was to tap the ledge at a greater distance from the surface, and connect the two tunnels (upper and middle) by an air shaft.

In July, 1879, only a month after the partnership was formed, Capt. Miller suddenly died. Shortly after his death this capitalist put a force to work under a superintendent to continue the middle tunnel, and as he progressed he became very enthusiastic over the prospects. Thinking he might secure the whole property to himself, he entered suit against Mrs. Miller (the widow of Capt. Miller), which resulted in his defeat, the entire property being returned to Mrs. Miller. From this time but little was done to the property until secured by the present owners in November, 1882.

The present owners propose to continue the middle tunnel, cross-cut and thoroughly prospect the ledge. Up to the present time about 175 feet have been driven and the prospects are very encouraging. Several stringers have been cut, one three feet wide, from which specimens were taken showing gold.

Favorable indications of the existence of a valuable ledge in this location are evident from the fact that in the bed of Washington Creek, directly at the base of the mountain in which is the Giant ledge, placer mining has been profitably carried on for over twenty years. It stands to reason that the gold must originate from the Giant ledge, for right here, where the croppings of the Giant ledge have fallen into Washington Creek, is the only place along the entire bed of the creek where gold is found.

Many fine quartz specimens showing gold have also been found in these placer diggings.

A water ditch is connected with the property. It takes its water from Washington Creek, about two miles above the mine, and runs directly under the middle tunnel; it will give a fall of 300 feet, almost perpendicular, at the mill site, which is near the lower tunnel, in the bed of Washington creek.

The famous Sierra Buttes mine, bought by an English syndicate in 1869, is situated only eighteen miles north of the Giant, on the side of the mountain. It compares almost exactly in respect to convenience of working the ledge, mill-site and grade of rock. A full description of the Sierra Buttes is contained in the MINING AND SCIENTIFIC PRESS of April 14, 1883.

With the prospects now apparent, the owners have great faith in the future of the Giant mine, and with careful management it bids fair to equal any mine in the county in size and wealth.

The Earth—Geological History.

[Written for the Press.]

Are we on the eve of a new era in the world's history, a new epoch, a catyielism of events, a wreck of matter and a crush of worlds? The year 1883 has been a year of disaster, and life with misfortune to the human race. Atmospheric, aqueous and igneous agencies have been unusually active. Their effects have been seen and felt in every quarter of the globe.

On the American continent cyclones, tornadoes and floods have occurred with their attendant results of loss of life and destruction of property, and attended by extraordinary electrical phenomena. Epidemics (the yellow fever) have raged with extraordinary virulence, both in Europe and Asia. In fact, from the whole civilized world we have detailed accounts of great losses by earthquake and volcanic action. Large areas with their inhabitants have been submerged, with corresponding elevation of "terra incognita." The "fell destroyer" has had a holocaust of victims, and the end not yet. Within the memory of man and his written history we have no parallel. Historical geology and traditional lore alone obscurely teach us of similar disturbances, prior to the advent of man. The great book of nature, when intelligently read by the scientist, unerringly points out the changes that have occurred since the formation of the earth we inhabit. This language, though dead, is easily read and interpreted by nature's student, the geologist. Much time and talent have been devoted to this subject. Quoting from a distinguished geological work which treats on "Historical Geology," the author states that the earth's history is divided into eras, ages, periods and epochs, which have been recorded by nature in separate rock systems, series, formations and strata. From indisputable evidence it is proved that there have been times of rapid revolutionary change, with periods of comparative quiet during which forces of change are gathering strength, followed by periods of rapid change during which accumulated forces produce conspicuous effects. The earliest era is the archæan, which is followed by four others, the latest being the psychozoic, in which we find the first authenticated evidence of pre-meval man and his implements of art.

Prior to this time animal life abounded in mammoth proportions in the cenozoic era, in which we find the tertiary and quaternary systems. The psychozoic era—an era of mind—is recorded in the recent system. The cenozoic was the culmination of the mammalian age. The most formidable in size was the mastodon, the mammoth and the megatherium—species long since extinct. Each era had its distinct classes of fauna, which on reaching the turning point of their existence, like the individual, gradually degenerated, or were violently and suddenly exterminated by a law of nature, that not only governs the universe with its immensity of systems and worlds, but their inhabitants as well—constant change, progression and retrogression.

MECHANICAL PROGRESS.

The Limitations of Machinery.

Not very long ago watchmaking was one of our most prominent industries—prominent not because the capital invested or number of persons employed in it was remarkably large as compared with many other industries, but from the fact that it seemed to offer a most striking illustration of the triumph of American ingenuity over all obstacles, natural and artificial.

Until we began to make watches the trade had been almost monopolized by Switzerland and England. The Swiss had attained a special celebrity for their skill in the art, and some English makers produced work equally good, but the Swiss watches, besides being well made, were very cheap, and consequently there were but few parts of the world in which they were not known and esteemed.

But the application of machinery and the factory system to watch manufacturing in this country caused a sudden change in the situation. The frugal habits of the Swiss workman, his simple diet of black bread and wine, his patient industry, even the rare technical skill which had been handed down from father to son through generations of watchmakers, were not sufficient to offset the ingenious machinery of the American factory—those marvelous machines, so wonderful in their accuracy and rapidity, never tiring, never making mistakes, needing not even the poor fare of black bread and wine, but content with the still cheaper diet of steam. It seems as if Switzerland's famous industry had seen its best days, and American time-pieces were to supersede all others.

It is a pity that a picture so pleasing to our national pride has not yet, and perhaps never will be realized. The American Consul at Geneva has recently made a report to our government on this matter of watchmaking, and from his paper it appears that in this industry Switzerland has now regained all the ground which had been wrested from her by our own manufacturers.

At a test of English, Swiss and American watches made recently at Geneva, under circumstances that forbid any idea of fraud or error, it was found that the Swiss watches were superior to all others, and the English came next in point of merit. But the Swiss watches were the cheapest as well as the best.

The explanation of this is very simple. The Swiss have taken our machinery and supplemented it by a manual skill and system of technical training which we do not yet possess.

The lesson of this is that mere machinery will not do everything. Skilled workmen must accompany good machines in every country which desires to excel in the industrial arts. It is worth while to emphasize these points, because many people, and among them quite a number of manufacturers, entertain the idea that American machinery is sufficient within itself to give us the advantage over all other nations. It is these persons who, believing that machines are all that is necessary, and that any cheap laborer will do to attend them, scoff at plans for the technical education of mechanics, improved systems of apprenticeship, and other reforms advocated by more intelligent and public spirited men.

Yet, as we see in this illustration from the history of watchmaking, we cannot hope to monopolize our machinery, and it is therefore of the highest importance for us to produce by means of a judicious system of apprenticeship and technical training a body of workmen as well versed in the fundamental principles of mechanics, as quick of eye and deft with hand as the men the technical schools of Europe are now turning out to compete with us.—*The Blacksmith and Wheelwright.*

Light Iron Castings.

Many years ago articles of cast iron of a light, fragile and ornamental character known as "Berlin (German) jewelry," were quite fashionable. It seemed, then, almost impossible that these should be simply castings of iron, and it is within a comparatively recent period that the possibility has been proved by the production of similar articles in this country. When of an ornamental design, as the shoe buckles, belt buckles, shawl clasps and hair pins, iron frequently has the market name of steel, and such "steel" ornaments are very common and in general use. But they are made of iron cast in sand moulds exactly as massive lathe beds, planer beds, and anvils for drop hammers, weighing several tons each, are cast.

The brilliant polish on the ornamental articles is produced by means of emery wheels, rag, rotten stone wheels and rouge wheels, prefaced by the action of the tumbling barrel.

Of course, only the easiest flowing iron is fit for such fine work. This is charcoal produced iron, that from the Salisbury mines in western Connecticut being admirably adapted to these purposes. There is an establishment in Connecticut that melts, for the purposes of minute castings, about ten tons of soft charcoal iron a day, casting scissars and shear blanks, clock bells, clock keys, drawer keys, door keys, piano tuning keys, rings, barress buckles, ornamental buckles, horsemen's spurs, and a hundred other

articles, not one of which will weigh twelve ounces, and many of which weigh less than an ounce. Some of these articles require in their finished state more than one hundred to the pound in weight. So minute are these castings, mainly moulded from plate patterns, that the used sand of the moulds must be sifted to discover all the results of the day's casting.—*Scientific American.*

A Process for Softening Iron Castings

A revolution in the manufactured iron trade is announced from Melbourne, where two local iron founders, Messrs. Jenkins and Law, are reported to have discovered a new process in their trade. It appears that an accidental discovery was the commencement of the invention; a fragment of cast iron having been dropped while hot into a water channel, and afterward broken, when it was observed to be soft and tenacious, instead of hard and brittle, as might have been expected. This phenomenon led to inquiry and experiments, with a view to ascertain the reason for the change. It was supposed that the temperature of the metal and the composition of the water were the principal circumstances which combined to produce the transformation; and, after numerous trials, the right temperature to which the iron should be brought before immersion was discovered, and also what foreign elements were required in the water. The metal is merely dipped in the bath, not steeped, the required change being physical, not chemical; and the ingredients of the liquid are common and cheap. As patented, the process is briefly as follows: The castings are run in a chill, or iron mold, allowed to cool, reheated in a furnace to a particular temperature, and then plunged into the bath. Thus treated, the iron develops a close, tough, and comparatively soft grain, so much like that of average steel that, according to the *Melbourne Argus*, experienced founders in the colony had great difficulty in believing the metal to be cast iron at all. By this process it is claimed that the adamant hardness of chilled castings is removed, and further positive advantages are conferred. This is saved by the great extension of chill castings for purposes to which their hardness formerly rendered them inapplicable. It is contended that the metal is also made much stronger; a bar that would break with a load of 1,200 pounds under the old system being capable, if made in the new way, of withstanding a strain of 1,900 pounds. Lastly, the soft, tough grain produced by the new process increases the facility of working the metal, with a corresponding diminution in the wear and tear of tools, and a finer appearance in the finished article.

EFFECT OF FURNACE GASES ON IRON.—There are exhibited in a museum in Darmstadt, Germany, some samples of round bar iron which have suffered a very peculiar change. These bars of iron were formerly placed within a large chimney at the Frankfurt gas works to serve as footholds as it became necessary to ascend the chimney. For several years they were exposed to the various gases at a high temperature, and probably there was among them plenty of carbonic oxide. At last the chimney began to bend and twist, rendering an investigation necessary, when it was found to be due to the increase in size of these bars.

They consisted originally of bars 2.3 centimeters (about 1 inch) in diameter, but have grown to be 3.3 or 3.5 centimeters (1 1/8 inch) in diameter. One was examined and found to have within a core 2.1 centimeters thick, surrounded by this external envelope that had been changed and enlarged. The *Gewerbeblatt* for the Grand Duchy of Hesse, from which we gain this information, does not venture any theory as to the probable changes or their causes.

THE SPRING CAR MOTOR.—The United States Spring Car Motor Co., of Philadelphia, recently exhibited its spring motor. It is stated that much interest was taken in the project, and that the company intends to go forward and prepare its motor for use in street cars and factories. The process involves the use of heat chemically pure and of great intensity. It is reached by mixing gas with air at the point of ignition, projecting the flame thus produced against the steel with great force. The steel thus rapidly heated to any desired extent, passes through the cams of the coiling machine and receives its coils. As it leaves the coiling roll, and within six inches of the last jet of heat, it is struck on each side by a blast of cold air with such force as to chill it, thus giving it the proper temper. A spray of water follows to remove the latent heat. A similar company is said to have been formed in New York.

COKE FOR FOUNDRY PURPOSES.—Coke is being successfully introduced for foundry purposes in New England and elsewhere, in preference to anthracite. The advantages claimed for coke over anthracite are: First, a duty 30 per cent higher than anthracite. Second, a rate of smelting from 30 to 50 per cent higher than that of anthracite. Third, a less powerful blast is needed. Fourth, the castings are softer.

A new glass recently invented in Vienna contains neither flint, potash, soda, lime nor borax.

SCIENTIFIC PROGRESS.

San Diego Natural History Society.

Probably there is no place, outside of the immediate vicinity of this city, where original research in science and particularly in natural history—is so diligently and effectively carried on as it is in San Diego. They have a fully organized and active society of natural history in that place, whose constant and efficient labors, though quietly and most unostentatiously conducted, are constantly adding to the world's store of knowledge. They hold regular meetings, the proceedings of which frequently find their way into print. The following officers were recently elected for the current year: President, Dr. G. W. Barnes; Vice-President, Joseph Winchester; Recording Secretary, E. W. Hendrick; Corresponding Secretary, Rosa Smith; Treasurer, C. J. Fox; Librarian, Mrs. Z. R. Cronyn; Curator, Dr. D. Cave; Directors—D. Cleveland, G. W. Barnes, C. J. Fox, E. W. Morse, J. G. Capron.

Several interesting papers were read at this meeting, among which was one by C. C. Parry, a historical notice of the *Pinus Torreyana*. It appears that this tree is confined to an exceedingly limited locality. As far as known it is found only on a small extent of coast line—not more than four miles in length, and extending only one mile inland. The locality lies between San Dieguito and a point about one mile south of Soledad, in San Diego county. Some interesting historical facts were given in relation to the tree, by Mr. Parry, who was the first to announce it as a new species.

The bulk of the tree-growth is mainly confined to a series of high broken cliffs and deeply indented ravines on the bold headlands overlooking the sea south of Soledad valley and within the corporate limits of the town of San Diego. Here, within a radius of not more than half a mile, this singular species may be seen to the best advantage clinging to the face of crumbling yellowish sandstone, or shooting up in more graceful forms its scant foliage in the shelter of the deep ravines, bathed with frequent sea-fog. One of the finest specimens seen reaches a height of nearly fifty feet, and shows a trunk eighteen inches in diameter at base.

Many collectors have visited this locality, and have taken away thousands of this well-marked new species to the remotest parts of the earth. The chair was instructed to appoint a committee of three to report and act upon such measures as may be deemed best for the preservation of the remnant of the *Pinus Torreyana* at Soledad.

Another paper was read by C. R. Orcutt, in relation to the recent additions to the flora and fauna of our State. The writer stated that since the last annual meeting over a dozen discoveries have been made in species of plants indigenous to this section, while many more have been discovered unknown hitherto in California.

The Corresponding Secretary, Rosa Smith, read some very interesting notes upon spiders. Particular mention was made of the *Epeira atrata*, in which she quoted from Dr. McCook as follows: At Aptos, near Santa Cruz, I secured an *Epeira* and cocoon of eggs and young spiders, which have revealed some curious facts in regard to insect parasites. Of these Dr. McCook writes: "One interesting thing about the *Epeira* cocoon is that it is strangely infested by parasitic and other enemies, no less than four. There were first a number of small reddish ants alive, probably a species of *Solenopsis*, which no doubt were feeding upon the eggs and debris; second, several larvae of *Dermestidae*, probably *Attagenus peltio*. These were creeping into the silky interior at will, though some of them were ensconced within the empty cells of some ichneumon. Next I found alive a very small ichneumon fly. I have never yet seen quite such a 'happy family' within the bounds of a spider's egg nest. The spiderlings seemed to be contented, and indifferent to the presence of these intruders."

The "Fourth State of Matter."

Mr. W. Crookes gave a lecture recently before the Western Microscopical Club, on "Recent Discoveries in High Vacua." He illustrated his theme with a series of brilliant and interesting experiments. The effects were produced by a large electric coil having 60 miles of secondary wire, and worked by two cells of a storage battery. The coil, when attached to its full complement of 30 cells, would give a spark in air of 24 inches. "High vacua" were defined as those ranging from above the one-thousandth to the one-hundredth-millionth of an atmosphere. Air and all gases are conceived to consist of myriads of excessively minute molecules, which, in the ordinary state, vibrate with enormous velocity; but, being crowded together in that condition, their extent of vibration is impeded by each other, and is, in fact, limited to a path of only one-tenth-thousandth mm. When, as in a partial vacuum, there are fewer of these molecules, they have more room in which to vibrate, and hence their "mean length of path" is increased.

Under the influence of electricity these molecules are driven in straight lines from the negative pole. In a comparatively low vacuum, on the passage of an electric current, the residual

air assumes a stratified condition, showing alternate light and dark bands. The width of the dark bands marks the length of the excursions of the molecules. Further exhaustion increases the width of these bands, so that in a vacuum of one-millionth of an atmosphere the free path of the molecules was seen to extend to about four inches. By means of an exhausted V-shaped tube it was shown that these molecules are driven from the negative pole in straight lines, and hence cannot turn a corner. First one limb of the V, then the other, was connected with the negative pole of the coil, with the result that each in turn was in darkness. In another vacuum tube, a concave negative pole was fixed, the molecules were driven normally from this concave surface, and, meeting the cylindrical surface of the glass enclosure, were thrown into beautiful caustic curves.

That these molecules, under the influence of electricity, possessed mechanical force, was shown by causing them to impinge on the vanes of a radiometer, when a rapid rotation took place. On reversing the current, the direction of rotation was also reversed. That this was not due merely to the passage of an electric current was shown by a vacuum tube containing a small horizontal "water wheel." Its upper and lower floats being struck equally by the radiant matter, no motion took place, but on diverting the flow of radiant molecules by means of the external application of a magnet, the molecules were caused to strike the upper floats only, when revolution took place. By reversing the magnet, the path of the molecules was diverted so as to strike the lower floats, and thus to reverse the rotation. Radiant molecules are not attracted by one pole of a magnet and repelled by the other, but tend to rotate round the north pole in one direction and round the south pole in the opposite direction. Hence, with a horseshoe magnet, they are deflected in a line at right angles to the line that joins the two poles. The mechanical effect of the impact of these radiant molecules was further shown by converging them by means of a concave negative pole to a focus in which was a small bundle of platinum wires. These wires were rapidly raised to a white heat by the vigorous though inaudible bombardment. Further, the impact of radiant molecules on certain bodies produces phosphorescent light; thus they give to potash-glass a green, and to lead-glass a blue tinge. If in an exhausted tube an obstacle, such as a piece of mica in the shape of a cross, be set up, a dark shadow of it is thrown on the positive end of the tube, the part surrounding the shadow being rendered phosphorescent by the impact of the molecules. On suddenly removing the obstacle, the part that was in shadow glows brighter than in surrounding luminous space. This effect is due to the molecules acting suddenly on a new, and as it were, untired surface.

DYING CUT FLOWERS.—It has for a long time been known that the color of growing flowers can be altered by simply mixing a little dyestuff with the mold in the flower-pot. No one, however, has hitherto thought of changing the colors of flowers when cut. We have in London many artists whose business it is to give to birds finer feathers than nature has allowed them, and we have now a counterpart in flowers. Mr. Nesbit, a distinguished botanist, has found that by simply soaking the stems of cut flowers in a weak dye solution, their color can be altered at will, without the perfume or freshness being destroyed. Most beautiful effects are produced by prepared lakes. Singular to say, flowers refuse to absorb certain colors, while they dispose of others in different manners. If placed in a mixed solution they make a complete analysis, and some lilies which had been treated with purple showed distinct red and blue veins, the colors having been divided in the process of absorption. [London Paper.]

AN INTERESTING EXPERIMENT.—During a recent lecture in the Philadelphia Academy of Pharmacy, glass jars were passed around containing samples of cultivated disease germs. Potatoes cut in halves had been lightly smeared with a coating of substances containing germs. The bacteria were nourished on the moist surface of the potato, and presented very interesting appearances. Different results were obtained from different bacteria. Some of the half potatoes were covered with an ordinary deposit of mold. On others the disease germs had developed into thin, peculiarly shaped patches of fungus growth of bright blue, red, yellow and greenish colors. Others had grown into an intricate and extensive network of fuzzy filers, the growth on the surfaces of two or three potatoes reaching over and covering a space having a diameter of eight or nine inches.

BACTERIA IN MOUNTAIN AIR.—Two scientific investigators, one Swiss and the other French, have been analyzing the Alpine air. They ascertained that entirely pure air is not found until an altitude is reached of from 6,000 to 13,000 feet above the level of the sea. The atmosphere around the lakes below that level, however pure and beautiful apparently, was found to contain bacteria. Nevertheless it was pure enough by comparison with that of the French capital, where the bacteria contained in a square foot of air are 7,000 times more numerous than those in the same quantity of air in one of the Swiss valleys.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MELIO CLAIM.—Amador Ledger, Jan. 16: We were shown last Monday a specimen of decomposed quartz taken from the quartz claim owned by the Mello Bros., and situated near Big Bar Bridge. The sample was speckled with fine gold, and would evidently assay far up into the hundreds. We are informed that the ore-body is from 7 to 8 ft wide, and if it carries gold throughout in the same ratio as the specimen shown us, the boys have struck a bonanza.

MISCELLANEOUS.—The rock of the South Spring Hill, now being crushed at the Talisman Mill, is panning out handsomely, so we are reliably informed.

Last Friday ten sacks of heavy metal, carrying a heavy percentage of gold, was taken out of the Julian mine at Middle Bar. The ore-streak holds its own.

Butte.

GOLD DUST.—Butte Record, Jan. 19: A big boodle of Butte creek gold dust was yesterday deposited in the Butte County Bank. The "perpetual injunction" does not interfere with the pick and shovel miners up in that region—they toil year in and year out, sometimes making a respectable strike, but nothing like a bonanza. The toilers are satisfied with their labor if enough nuggets can be collected to furnish the actual necessities of life. In some of the camps in this county are still to be seen old-timers who are yet working in the vain hope of striking it rich. They are still the rough, kind-hearted, red-shirted fellows they were in the days of old.

Calaveras.

LAND SLIDE.—Calaveras Chronicle Jan. 19: There was a large landslide in the Bonanza hydraulic claim on Tunnel Ridge, owned by Moser & Co., Saturday last. Nearly an acre of ground came down into the claim, covering up the "Giant nozzle" and all the tools in the mine to the depth of twenty feet. The "slide" also carried away nearly 200 feet of the ditch owned by the Mokelumne Water Company, and through which water is run to supply the Mammoth hydraulic and other claims further down the ridge. A large force of hands were immediately set at work constructing a new ditch.

PROSPECTING.—Prospecting is being vigorously prosecuted on the leads recently located on this side of the Mokelumne river at Middle Bar, and owned by Sales, Reed & Co. Sinking on the ledge is now being done and the developments thus far made are of an extremely encouraging nature.

NUGGET.—Mr. T. S. Loutit, the Lafayette Street Vulcan, found a \$90 nugget one day last week. It is a common occurrence in this place, after a heavy rain storm, for people to pick up in the streets chispas varying all the way from a \$1 to an ounce in weight.

El Dorado.

LAMPHER.—Mountain Democrat: The incline at the Lampher mine has reached a depth of 245 ft. Drifts are being sunk north and south from the bottom. In the north drift, which is in upwards of 40 ft, the vein is very wide, ranging from three to four ft. In the south drift the vein is about fifteen inches in width, but is widening as progress is made. The ore is very rich. The mill is running steadily, with good results.

Fresno.

GOOD YIELD.—Expositor, Jan. 16: Thos. Hildreth yesterday brought to town about ten pounds of gold amalgam which was taken from ten tons of ore from his mine worked by process. The ore was from the sloping of the 10-foot level. The yield was at the rate of over \$200 per ton. He also showed us a vial containing about an ounce of fine gold which was washed from a single pan of decomposed ore. The ledge is only about fourteen inches in width, but it is very rich, and seems to be getting better as they sink on it. The gold is heavily alloyed with silver, and therefore does not average more than \$12 per ounce in value. This is a characteristic of all the quartz mines of this county, and it seems to be the impression of many miners that after a certain depth is reached silver will be the predominating metal.

Inyo.

WILD ROCK.—Inyo Independent, Jan. 16: This old district is situated in the Telescope range, across Panamint valley from Lookout. The Virginia mine, owned and being developed by Paul Pfeiffer, is showing up splendidly in chloride ore assaying from 150 to 450 ounces per ton in silver.

SWANSEA.—The new Swansea furnace is in full blast, the bullion output being all that could be desired.

THE MONTEZUMA.—Supt. W. P. Miller, of the Montezuma mine and furnace, (the Owens River Mining and Smelting Co.) is now at Elina. Their own mine has on its dumps about 4,000 tons of ore, while shipments of all kinds of ore are being steadily received from all along the line of the road.

THE RED MINE.—It is stated that the owners of the Mineral Hill mines, situated at the head of Black Canon, in the Inyos, are getting out ore to ship for reduction.

BULLION SHIPMENTS.—Supt. M. R. Williams, of the Argus Range M. & M. Co.'s mines and mill at Reilly, was in town to day. He reports having got the mill in good working order, and that everything about the plant is in a most satisfactory condition. He has lately made three shipments of silver bullion—668 fine—aggregating \$70,500. The property is becoming a steady and reliable producer of bullion.

Mariposa.

O'GORMAN.—Gazette, Jan. 17: The new ten stamp, steam quartz mill of the O'Gorman Brothers, on Saxton's creek, started up last Wednesday. The new "plant" has attracted considerable attention from the community, all hopeful, as well as its enterprising owners, that it will be a success. There is already upon the dump about 100 tons of ore which shows free gold sufficient to give assurance that the rock is, by proper amalgamation, going to pay well, at least \$20, and probably \$30 a ton. Quite a number of men are already employed and assigned to

duty. Among them we learn that Joseph H. Green is to have charge of the amalgamators. Mr. Green is just the man for that position, having had a large experience as a mill man and amalgamator, and for industry and integrity he has the confidence of all who know him. The other employees in and about the mine and mill are Joseph R. Green who is to perform the duties of engineer and fireman, on opposite shifts with Wm. O'Gorman. Jos. Milburn is teamster and contractor for hauling the rock to the mill, a distance of three-fourths of a mile. Wm. Richards, John and James O'Gorman, with George Stewart at the windlass, constitute the mining force. The rock is at present taken from a drift about 35 ft below the mouth of the shaft. With large quantities of ore in sight, easily mined, the vein being large, and easily crushed, it looks as though a prosperous and permanent mining enterprise is an established fact.

Mono.

IMPROVED PROSPECTS.—Bodie Free Press, Jan. 16: The last few weeks have materially improved the prospects of Bodie district—in fact, at no time for over a year have they looked as well as now. The rise in Bodie stock is not caused by manipulation, but is the result of substantial merit in the mine. The Standard now comes to the front with a very important strike on the 700 level, where up to the present time there has never been anything of value. An east cross-cut has intersected the ledge at a point north of the shaft, and the vein is found eight ft wide, of good milling ore. No ore has ever been extracted between the 500 and 700 levels, so that there is now ascertained to be 200 ft of backs in this ground. It is unnecessary to point out the fact that this is a most important development, the value of which it is difficult to estimate.

Additional to the strikes in the Bodie and Standard, which are the most valuable that have been made in the district for over three years, the Syndicate is now milling better ore than ever before, and last month made larger bullion shipments than during any previous month in its history. They have also a large supply of this ore developed. The Bodie Tunnel Co. will have their mill running before the week is out, and they also have plenty of good ore in sight.

The bullion shipments during 1883 have amounted to over \$1,500,000. In 1884 we predict they will be nearly if not fully doubled—a prediction based upon the present appearance of things and facts within our knowledge. With the beginning of this year, Bodie entered upon a new and better era in its history.

Nevada.

GOOD.—Nevada Herald, Jan. 17: Rock which yielded \$75 per ton, exclusive of sulphurets, was taken from the Magenta mine, near Grass Valley, recently, by tributaries. More of the same kind of quartz is in sight.

RICH STRIKE AT THE FRANKLIN.—A remarkably rich strike was made last Monday morning by Hussey & Hussey in their mine (the Franklin) in the Willow valley portion of this township. The ledge which has averaged about three ft in thickness and been of high grade from the surface to the present depth (160 ft) where it measures about 17 inches, is now showing richer than ever. From three tons taken out since the first of the week in sinking the incline, were selected three candle-boxes of specimens that will apparently pay at the rate of not less than \$5,000 a ton. One old quartz miner stands ready to bet a nice little sum that they are worth even more than at that rate. More of the ledge is now being stripped for extraction and the richness shows no signs of abating on either side or at the bottom of the incline. Another level is to be opened at a depth of about 250 ft. The drift at the first level has been driven fully 100 ft along the ledge and the end of the pay chute at that point has not been found in either direction. The indications are now that the Franklin will prove to be one of the best quartz mines in the district. A few more weeks' prospecting will demonstrate its true value.

PITTSBURG MINE.—Grass Valley Union, Jan. 17: The completion of the drain tunnel to the Pittsburg mine will be the means of starting up the machinery of this favorite mine within a short time. This tunnel, which is 800 ft long, and has required two and a half years to drive it through hard ground, taps the mine at the bottom of the 200 level, from which depth to the surface nearly all the water comes. Below the 200 level the mine does not make much water, as in sinking for the 800 level several years ago the water was found so light that it was not necessary to use a workings, boxes will be put in through the full pump. Now that the tunnel has reached the old workings, boxes will be put in through the full length of the 200 level to catch the drainage above, which will admit of the levels below being worked with but little pumping. It will take about two months to do this work, when the machinery will be started up and regular operations of mining and milling resumed. There is good ground opened in the Pittsburg, and the mine was looking very well when it was shut down for the running of the drain tunnel with a view to more economical working in the future. The Pittsburg has been a good bullion producer in the past, and has long life in it yet.

THE MAGENTA MINE.—Grass Valley Union, Jan. 16: The drifts on the 400 level of the Magenta mine, which were started a few days ago, have been extended ten ft to the north and six ft to the south. One "taken up" of ledge has been made in the north drift, and the quartz shows of excellent quality. The quartz that is being stoped above the third level is also of good quality. The rock coming out of the shaft from which the crushing of \$120 per load was made a few days ago, continues to show richly in free gold, and the next cleanup from there is expected to show a fine result. The Magenta is showing up well in its workings, and there is every reason to believe that it is going to develop as a valuable property.

RICH STRIKE.—Herald, Jan. 19: Last Monday a strike of unusual richness was made in the Franklin mine, owned by Hussey & Hussey, at Willow Valley. A blast in the face of the incline uncovered a fine body of ore, from which many exceedingly rich specimens were taken. From three tons of rock were selected three candle boxes of specimens, which, it is estimated are worth at the rate of \$5,000 per ton. The ledge is seventeen inches wide, well defined, and the general indications are most flattering, giving evidence of permanence and continued richness. At the 100 level considerable prospecting has been done with encouraging results, the ledge

being traced upwards of a 100 ft without disclosing the end of the pay chute in either direction. At present the incline is down something over 160 ft. When a depth of 250 ft is reached, another level will be opened and the working force increased.

Placer.

A GOOD CLEAN-UP.—Placer Herald, Jan. 16: George Keehner sent to the mint a few days ago 27½ ounces of gold, the result of a recent crushing of about 20 tons from the New York mine. The New York is an eastern extension of the old Conrad, and for the amount of work done on it has panned out very well.

S. F. COPPER MINE.—Tidings, Jan. 17: We learn from Dr. M. P. Harris, who has just returned from Spenceville, that a new vein of copper ore has been struck in that shaft of the San Francisco copper mine at that place. The old vein had been worked out, and a shaft started which is now down 180 ft. The new vein is said to be richer than any heretofore found in this part of the country. The hoisting engine at the mine was broken last week, and in consequence, the employees will remain idle until repairs can be made.

A RICH CRUSHING.—Grass Valley Union, Jan. 17: The first crushing of quartz from the Magenta mine was cleaned up at Sothorn's mill on Tuesday, and the result was \$480 from four loads of rock, or \$120 to the load. The rock was taken out by tributaries, who although they expected a fair yield were astonished at the going up to such splendid figures. The Magenta stockholders were feeling very good over this "prospect" yesterday, as they saw visions of coming richness in the mine that gives such good promises.

THE NORTH STAR MINE.—Grass Valley Union, Jan. 16: On the authority of one of the owners of the North Star mine, it is stated that the famous old mine will be started up again during the present year. The mine, first and last, was a big producer of gold, and in the last month of its operations paid more than expenses, and why it was shut down "is something no fellow can find out." There is plenty of new ground in the location that has never been worked, and it is the common belief of working miners who are acquainted with the mine that it is yet a valuable property.

Plumas.

ENCOURAGING.—Greenville Bulletin, Jan. 19: At the Gold Stripe a very encouraging prospect has been found in the Bidwell tunnel. This is a part of the ground that has not before been prospected. In the Green Mountain tunnel the character of the ground has been changing for some days past, and is now of that appearance which indicates that the Blake chimney is not far off. Two weeks or so more and the vault will be opened, the treasure got at. At the Halstead mine, Rich Gulch, the tunnel has not yet reached the ledge, though the face of the drift is beyond where it was expected to be found. At their claim near Soda Bar, John Riddle and his partner have plenty of water to work with, and are running steadily. They have now been piping for some time, and are satisfied with the result. They worked very hard to get ready for piping; all of their material, their pipe and lumber for flumes, they carried on their backs not less than two miles over a country where neither horse nor mule could go, two men taking one piece of pipe at a time and making four trips each day.

EAST BRANCH.—Plumas National, Jan. 17: From a letter received a day or two ago, we take the following mining notes: "Most of the claims are idle for the want of water. Brooks' mine is the only one at work. Gifford and Doe Leonard, at the mouth of Deadwood, are in about 70 ft with their tunnel. They are in lava and are hunting for an old gravel channel, which they expect to find this spring. They are well prepared for work, and intend to stay until they do find gravel. The tunnel in the Halstead mine is in 270 ft, but has not yet cut the ledge. Will send you an item occasionally when anything turns up."

Shasta.

GOOD.—Shasta Courier, Jan. 19: The twin quartz edges owned by Frank Yung and partners, located at Quartz Hill some time ago, continues to show the golden glow, and is indeed a bonanza. The owners are the lucky miners of the season so far, and at last accounts were hiding in a tunnel on account of it being Leap Year and the attractions which wealth has for the crinoline persuasion.

Sierra.

A PROMISING CLAIM.—Mountain Messenger, Jan. 19: Bald Mt. Extension Co. have 36 men employed, and over 2,500 carloads of pay gravel in their large dump, presumed to be worth at least \$6,000. The cleanups thus far this month have amounted to near 200 ounces. The main tunnel is now in the lava flow over 200 ft, and is being steadily pushed ahead by the contractors, S. Stephenson and W. Deeds. The general belief here now is that on the other side of the lava the lead will be found on the Extension ground, near which, as the channel is worked in the South Fork, the richest gravel is being taken out. In gangway No. 4, water has been tapped, caving part of a breast, and unsettling the gangway timbers, deemed an evidence of near proximity to the lava flow. A two-ounce nugget was found in one of the breasts the other day, and another was picked up in the sluice of the large dump last Monday. The gold from the South Fork since the lead was found bending in there from the Extension, April 30, 1883, to the close of the year, eight months, has been over 3,055 ounces, and sold to Charles Heintzen for \$18.60 an ounce, \$56,834.70, averaging a little over \$2.60 per carload. Pay roll, \$25,873.61. Dividends, \$18,949.85. The works are in first-class order, and kept in good repair. The main tunnel is in near a mile, 3,400 feet of which is in an air-line, except a slight bend to the left a short distance below where it turns up the ridge. The trains of a dozen cars or more are hauled out by mules. The lava flow, now being crossed by the main tunnel, covers what is undoubtedly the extension of the Ruby channel, of which there must be at least 2,000 feet on the Extension ground, that will probably be in time developed with an incline. Pieces of decayed trees are daily found in the lava, and last week some cedar bark was disclosed, natural to life. Under the able direction of Superintendent W. Lawry, and his efficient night foreman R. P. Mott, this valuable mining property, one of the most promising in the gold belt, is being thoroughly developed

in a systematic and economical manner, creditable to the management and stockholders.

COLUNBO.—Downville Tribune, Jan. 17: At the mine there is only a little snow lying in patches here and there. The mill will be cleaned up to-morrow. Up to that time 350 tons of ore will have passed through the batteries. The plates both inside and outside of the screens are showing up splendidly and the result of the first clean-up is pretty sure to prove even better than had been counted upon. The sulphurets that come from the Frue concentrators assay from \$687 to \$703 per ton. The percentage of the sulphurets yield will doubtless increase as depth on the ledge is acquired and from their rich character will eventually play an important part in the product of the mine. A little trouble has been occasioned by the scarcity of water for milling purposes, but this will be obviated shortly as the flow of water from the lower tunnel increases. The lower tunnel is going ahead toward the vein which will probably be reached ere many weeks longer.

RUBY.—The Ruby Co. have forty-four men employed. Two inclines are down, and three breasts being worked. The west rim of the channel has been found, and the lead crossed 150 feet in search of the east rim. There is sufficient water to wash all gravel taken out, so rich in the breasts and gangways that gold is easily seen in it most everywhere. Pay loads average each about \$2.50. Pay gravel averages two and a half feet in depth. A large force will be put on soon as water comes. Snow is fifteen inches deep at the mine. Clean up last week was 55 ounces and 2 penny-weights, and the one before, 41 ounces. Under the able direction of Supt. J. Colman this valuable mining property is being thoroughly developed, and promises to prove a most remunerative investment for its fortunate owners. The pay roll for December amounted to over \$2,000.

The Bald Mt. Co. have one hundred men busy in their mine and the dumps are well filled with gravel, awaiting water. H. W. Wallis, Supt., anticipates a good clean up.

Trinity.

CLEAN UP.—Shasta Democrat, Jan. 17: Day & Moore, of the East Fork ledge, made a very encouraging and handsomely clean up at their claim the last of this week. From H. Meckel, who had just returned from there, we are informed that out of nine tons of rock they realized over \$900. They were compelled to quit work, owing to the cold and frosty weather.

PAID WELL.—Journal, Jan. 17: Henry Meckel tells us that Day, Moor & Hubbard, on the East Fork, made a clean-up last week after running their arrastra seven days, and that they took out enough to pay all expenses for the season. The quantity of rock crushed was about nine tons, and that it yielded at the average rate of \$100 to the ton. This is a working test that proves the richness of East Fork quartz, and will result in stimulating prospecting in that district. It is a promising held.

DEADWOOD ITEMS.—A correspondent at Deadwood furnishes the following items from that section: "This camp is very lively at present, as all the arrastras are running and the steam quartz mill is hammering away again. The mines are all getting out quartz, and some of them very rich rock. Mr. and Mrs. Lambeth have returned from the city, Mrs. Lambeth having been absent at the East for about three months on a visit among relatives and friends, and says she enjoyed the trip very much. Mr. Murdock has returned, paid off his hired men and a portion of the purchase money on the Philip's mine on the French gulch side of the mountain."

Another correspondent writes from this section as follows: "The old mines being worked here are well known to be rich, so it is useless to speak about them. I visited a mine yesterday owned by Jacob Paulsen and Alex. McGregor. The latter gentleman kindly showed me through the mine and prospected some of the rock which was 'way up.' M. Chudbourne and a man named Cox have a good prospect in a vein of quartz about four inches wide, just above Paulsen & McGregor's mine. Mr. Cox is about to bond his mine, which is a late strike, to W. L. Roberts, of Oakland, who was on the ground to-day. Mr. Kelly has good rock in his mine with a four-foot ledge. Mr. Collopy has a very rich vein, though small, but it is getting larger as he goes down. The Isola quartz mine, owned by Isola and Frick are driving in their tunnel which is expected to reach the big bonanza the last of the month. The Mountain Chief, owned by Weldon and supposed to be an extension of the same ledge on which the Isola is located, has a fine prospect and will commence to open up in a few days. Wm. Blagrove has a good prospect on an extension of the Frick & Davis mine."

Tuolumne.

QUARTZ.—Tuolumne Independent, Jan. 19: Mr. James Tulloch and sons have several good quartz claims on the Brown's Flat slope of Bald Mountain. From one which they are now developing they have taken between \$11,000 and \$12,000, and it is now paying well. The chute is 175 feet in length. The shaft is 200 feet in depth, and they are still sinking on the vein, which is from six inches to two feet in width. A milling vein on the other side of this prospects well and is doubtless very valuable. Neither of the claims are for sale, which gives force to related facts.

NEVADA.

Washoe District.

GOULD AND CURRY.—Enterprise, Jan. 19: The Bonner shaft has been put in good repair down to the 1200 level. At this point the main north drift will be cleaned out and repaired up to the Con. Virginia line. The shaft will be repaired all the way down.

ALTA.—They are now about ready to resume work in the face of the east drift on the 2150 level at the point where it was dropped at the time of the flooding of the mine. This work will be followed with great interest by all the mining men.

UNION CON.—The main north and south drifts on the 3100 level are nearing each other, at the rate of over 50 ft per week. The sound of the drill working in the face of one drift can be faintly heard in the other, though there is a great breadth of rock between the two points.

SIERRA NEVADA.—The northeast drift on the 3100 level is making good progress, and the face is still in ore of low grade.

MEXICANS.—General repairs are being made and

the mine is being put in thorough working order from the 2500 down to the 3100 level. By the time the connection is made in the drifts on the 3100 level of the Union Con. they will be ready for active prospecting operations.

BEST AND BEGHER.—The ground in the bottom of the joint Gould and Curry mine below the 2500 level is still very soft, and requires close watching and timbering.

ORRICK.—The usual amount of ore is being extracted on the 150 level, and the winze is going down at the rate of over 20 feet per week.

CROWN POINT.—Owing to the low stage of water in the Carson river, the freezing up of the wheels of the mills, and other troubles, a full force of men can not yet be put to work in the mine, however, all the ore that can be crushed is being extracted.

HALL AND NORRIS.—The winze below the 2700 level is fast nearing the 2800 level, where a station will be opened and prospecting commenced. The material at the bottom is of a very favorable appearance.

COMBINATION SILVER.—The new hydraulic pump continues to give perfect satisfaction. During the past week the air compressor has been thoroughly overhauled and is now doing excellent work.

UTAH.—The northeast drift on the 1750 level is being advanced at the rate of over 40 feet per week. The quartz in the face is improving and is now giving low assays.

Bristol District.

TEMPER. *Pioche Record*, Jan. 12. The Temper mine of Bristol district has been relocated. This is one of the best, if not the best, mines in the district. There are many hundred tons of a fair paying quality of ore in sight, and it was the principal mine in the series formerly owned by the Gilmer & Salisbury Co., but which has recently been changed to the Iron Silver Co. Two men were sent to the mine for the purpose of doing assessment work, but instead of working on the Temper, they worked on the adjoining claim, known as the Red Cloud. On the 2d of January, old Uncle Abe Rickard relocated it, and he has a perfect title.

Eureka District.

LOCAL NOTES.—*Sentinel*, Jan. 17: Waters & Co. are shipping quartz ore to the Richmond furnaces for flux. The fourth of July mine has been leased to George Andrews and brother. The Clipper mine on Home Ticket Hill is producing ore carrying from 20 to 50 per cent lead. The tributaries in the Hamburg mine are still successful, and are making dividends for the company. It is understood that the E. & P. R. R. Co. will make special rates for ore to Salt Lake. Martin Planton has made another strike in the Dead Broke, the richest ore ever found in the mine. Messrs. Lane and Jenkins have struck a body of rich ore in the Excelsior mine, which they leased lately. The rich ore streak in the North Addition Chamber of the Eureka Tunnel, gives evidence of still further improvement. The prospects for pay ore in the Uncle Sam mine, on Peelsick Hill, are very good—red lime and iron showing up abundantly. Much of the preparatory work at the Connolly mine has been completed, and the resumption of developments will shortly take place. The 200-level of the Eureka Tunnel is in a fine prospecting condition, and if a force of men were employed it would very probably show up a good deal of ore.

Highland District.

HAMBURG.—*Pioche Record*, Jan. 12: This old abandoned mine, which has not been touched for years, with the exception of having several years' assessment work done on it, which is located in Highland district, and was purchased by the Day Co. for \$150, has come to the front. Two men, after the purchase of this mine, were placed at work prospecting, and in running a drift from the bottom of the mine, encountered a vein of ore nine feet in width. The assays from this ore go as high as \$150, but we are of the opinion that the assays were made from the best of the ore. The ore vein is nine feet across—strong—and the ore will average, it is thought, fully \$40 per ton. If work was only done on a number of the old abandoned claims along the range between Pioche and Bristol, there would be a number of valuable mines opened up. If the prospectors would do more work and less talk, their fond anticipations might be realized.

Schroeder District.

THE NEW MINES.—*Elko Free Press*, Jan. 19: Professor Birner and Mr. J. E. Gilligan have been on a prospecting tour over in Schroeder district, about twelve miles west of Carlin, and report the outlook fine for a good camp as soon as the snow leaves. There are two mines, the Comstock and Grace Darling, being worked by a Chicago company. The latter has a fine body of ore in sight, with over 500 sacks on the dump, and one man is taking out 40 or 50 sacks daily. Part of this mineral belt lies in Elko county, and the line should be established as soon as possible, so that prospectors will know where to record their claims.

Tuscarora District.

WILL. CLOSE, DOWN.—*Times Review*, Jan. 14: The Grand Prize mill will close down some time this week, or as soon as the stamps catch up with the ore dump. The supply of fuel has been reduced as low as the Supt. considers it safe, in view of keeping a sufficient quantity on hand to run the hoisting works during the winter season. The work of extracting ore from the stopes will be continued and new ground opened, preparatory to another run when the supply of fuel is renewed.

White Pine District.

HAMILTON'S PROSPECTS LOOKING UP.—*White Pine News*, Jan. 16: The latest advices from Hamilton are that the mining outlook for the coming season is brighter than for years past. Mr. J. R. Kendall, since his return, has put a force of men to work on the Jennie A. and talks of starting up a furnace by the 1st of April. It is also believed that E. N. Robinson will resume operations on the Sweetwater Co.'s mines early in the spring. All of which prospective good fortune we hope our neighbors will have in due time.

ARIZONA.

PINE SPRING MINE.—*Prescott Courier*, Jan. 14: J. M. Roberts, one of the owners of the Pine

Spring mine, is in Prescott and says that it is the intention of himself and partners to procure hoisting machinery and go down deeper in the mine. They are now tunneling and propose, when they feel like using some more cash, to take out several tons of high grade ore.

QUINTOAS.—*Cor. Los Angeles Times*, Jan. 13: The sale of the Quintoas bonanza mines to Messrs. Mackey and Flood has caused an undue excitement, and many people are acting without reflection and hastening there as if every hill contained a vein of precious metal and a thousand capitalists were waiting to buy every location. It is true that some facts about this 12,000-acre sale are encouraging. The ore is rich. The smelters have given returns of \$8.50 per ton, on the average. Assays run from \$250 to \$1,100 per ton. Any of the rock of the bonanza hill will go \$53. It is true that the bonanza companies will put up mills and work these mines and employ a great many men, and that another Virginia may arise on the new Comstock. There is another side to the question. There is only one bonanza hill, and it is all owned by one company. It can only be climbed in one place, and that place is guarded. The ore is free milling and easily worked. W. C. Davis, one of the original locators and a part owner, says that at the utmost there will not be over 200 men employed on the hill, and not over 100 by next summer. Thirty men are at present all there are employed, and they are digging a trail up to the mines. Then there is the water question, which is yet to be settled. The Bonanza company is boring, but it has not struck water yet. Another serious question is that of wood. This supply is very limited in the immediate vicinity, being nothing more than the brittle mesquit, that can be chopped with a hoe. As it is, people are rushing to the Quintoas by the fifties and hundreds every day, with bags and baggage. It is a harvest for the hotel-keepers, the freighter and the corral man. There is nothing else to do but prospect, and the hills are already full of keen-eyed men searching for minerals. There is nothing to employ the great crowd, who are rushing there "a little too previous." Many cannot afford to wait, and others will consume their little capital in waiting. All cannot get employment, and all cannot get bonanzas. A majority will get borascas instead, and then they will return sored, and "give the place a black eye." The way the people are coming here shows the character of the Pacific coast has not changed in the past 35 years, and that its people have not profited by the Gold Bluff, Frazer river, Boise, Washoe, White Pine, Panamint and a dozen other wild-goose chases after phantom fortunes.

COLORADO.

COAL.—*Register-Call* Jan. 12: The output of Colorado for 1883 is estimated at 1,114,040 tons. Of this amount the Welch mine at Louisville is credited with 103,321 tons, the mines at Langford with 45,000 tons, and those of Erie and Canfield are lumped at 80,000. This would make Boulder county's coal output a trifle less than 200,000 tons, between one-fifth and one-sixth of the entire state, and this at \$2.25 a ton foots up \$450,000.

GOLD.—The first shipment of gold retort made by the banks of the city for 1884 was made by the Rocky Mountain National Bank, amounting to \$3,500. The shipments for next week will be large, as there is considerable gold held over, and that coming in will help to swell the aggregate.

HUBERT.—The lessees of the Hubert mine, Nevada district, received for a car-load of smelting ore shipped to Denver a few days ago \$45 per ton net, an advance of \$20 per ton over former prices. The mill dirt treated at the stamp mill in Black Hawk for the month of December 1883, gave an average yield of 5 ounces gold per cord. Mill men treating the ore report that the plates are looking much better, and the average for the present month is anticipated will be 7 ounces per cord.

IDAHO.

FROM SPOKANE.—*Cor. Bedrock Democrat*, Jan. 10: I have started for the mines and have turned back on account of a snow storm. I am very glad I came back for I was not very well prepared for a trip of that kind. I went as far as the agency and could not get any one to pack grub in to the mines for any price. They are asking 25 cents per pound for packing. Everything is 75 cents per pound in the mines and scarce at that. Diggings as rich as mud. No discount on the mines and lots of ground to be worked.

COEUR D'ALENE.—*Helena Independent*, Jan. 13: John H. Brown who has just arrived from the Coeur d'Alene mines, says that at present they are inaccessible, except to pedestrians, and even then the trip is one fraught with suffering and danger, the snow being very deep on the ranges. There are now about 500 men at Heron siding waiting an opportunity to go into the mine. There are also a good many men at Rathdrum and at one or two other points, from which it is expected that trails will be opened. About 200 men are wintering in the camp. Every article of food is high, flour and bacon selling at almost any price that may be asked, and other things in proportion. The twenty-acre claim rule has been broken up, and now all that one claimant is allowed is a one hundred foot strip, extending across the gulch, which is about 50 yards wide. The ground is so flat (the fall being from only one to one and a half inch to the rod) that shieling is impracticable. Mr. Brown regards the Heron Siding trail as a very dangerous one for stampedeers to attempt to follow, at least until the snow is all gone and the trail is thoroughly opened. Many persons have tried the Heron trail, but generally have failed and had to come back and go round by the way of Rathdrum and Fort Coeur d'Alene. The Heron trail has never been free from snow, and at present the snow is from three to ten feet deep. The distance across is not so great, for at times the tooting of the locomotive can be heard at camp; but the ruggedness of the country and the heavy growth of timber (which keeps the snow from melting till far into the summer) render it a very undesirable route to get to the mines. Some assert that a good trail can never be opened from there. On the contrary, the route by way of Rathdrum is generally almost free from snow, except in the severest weather. A small steamer, now being built, will operate to the mouth of Eagle creek, but this will probably only last during the spring rise. During its continuance this route will doubtless be the favorite one. Notwithstanding the depth of snow there are more people still going into the mines than

are coming out, but it is unwise for those intending to go to risk the hardships of the winter trail. Shortly before Mr. Brown left, new and rich diggings were reported to have been discovered in Fourth-of-July canyon, and other localities are being prospected as fast as the weather permits. Miners generally expect a big boom in the spring.

STRIKE AT LAST.—*Wood River Times*, Jan. 16: The gratifying news comes that the miners working in the Mount View mine, near Bullion, struck the ledge last week and found it to carry a vein of solid galena from one to two feet wide, which carries from 600 to 700 ounces of silver per ton. The ore is exactly the same character as that of the great Bullion vein, but it is of much higher grade in silver. The Mount View claim was located over three years ago, by Barney Quigg and Dan Colman; Judge McBride and Moses Hirschman, of Salt Lake City, were also interested. These gentlemen afterward bought out Mr. Colman, so that they became the sole owners with Mr. Quigg. They then began prospecting, and have since expended all of \$20,000 on the claim, with but insignificant returns. Now that they have struck ore, however, they will doubtless be amply repaid for their outlay.

MONTANA.

NOTES.—*Inter-Mountain*: Doc Larkin has a force of men at work on the Bob Ingersoll lode, and the shaft is down twenty-five feet. The water is coming in fast and a night shift will be put on this week. The lead gives promise of being rich and is the property of Doc Larkin and Ed. Stack.

On the Ramsdell Parrott ore is being raised from the stope on the 200 level. About thirty tons are hoisted daily with a whim. The main shaft is down 300 feet. East of the main shaft another shaft, six feet across, is being sunk on a body of free-milling ore, which is to be tried this week at the Dexter mill. Samples all the way across give a return of eighteen ounces. The copper ore is still being hauled to the Montana Copper company's smelter.

QUARTZ DISCOVERIES AT WASHINGTON GULCH.—*Helena Independent*, Jan. 10: Robert Hodge, of Meadow Creek, says that the find of rich quartz made on the head of Washington gulch last fall promises to cause quite a stampede there in the spring, and it is thought by those competent to judge that some rich developments will be made as soon as the irrepresible prospector can get in in the spring. As the find is above timber line no prospecting can be done at present.

BUTTE.—*Miner*, Jan. 12: To one unaccustomed to the scenes of activity which constantly prevail upon the now snow-clad mountain spurs, lying north of Butte, the busy aspect which they now present would prove a surprise. The hills and gulches are crossed in every direction by well broken roads, which wind about the various properties, crossing intersecting and diverging from each other in a thousand different directions, while hundreds of heavy teams laden with wood, mining timbers, lagging and other supplies wind along their course. Upon every hand, in every gulch, on every spur and apex, may just now be seen the claim owner of abiding faith, patiently engaged with shovel, pick and barrow, doing the assessment work which Uncle Sam exacts as the condition of holding the claim which is some day to become a great mine.

The great south vein ore body of the Alicer mine, which has been developed in the east drifts from the one, two and three hundred-foot levels, was penetrated last week in the 400-foot drift, where it shows width of three and a half feet. The south vein is one of the most reliable and uniform ore shoots ever developed in this district. In each of the upper levels it has been stripped for a horizontal distance of from 350 to 400 feet and explored by winze to the level below and has been found throughout its entire extent to maintain its uniformity of and width grade.

The Lexington mill continues its steady run and satisfactory output, opening the ball for the new year with a shipment of \$42,304 last week! At this rate the lucky Parisian stockholders may expect another \$250,000 dividend in the near future.

Active operations are continued in the northwest drift from the 100 of the Bell. The new strike improves in width and grade with development. It is expected that the smelter will be started up on ore from the stopes of the 400 in a few days.

NEW MEXICO.

KINGSTON.—*Herald*, Jan. 10: We had the pleasure of again visiting Kingston and spending a couple of days there last week. The lull after the activity which preceded the new year, due in part to the general working of assessments, caused the merchants to speak of it as dull by comparison, yet there is everything to encourage the people, whether business men or miners. The town has grown some and a number of new buildings are in course of erection, while many others have been added to or improved. The mines of the camp are its hope and its chief reliance, and their condition is one of steady improvement. It is the output of a mine which attests its value, and according to its age Kingston has more actively producing mines than any camp in the Territory; indeed, we are not certain if it has not more than any camp of any age. The Bullion is showing steady improvement. The hoisting of ore has been in large part suspended while they have been sinking and upraising a large double compartment incline as a working shaft. Connection was made in it on the 31st, and the entire shaft is opened and timbered to a depth of 134 feet. The machinery was arriving on the ground and the boiler was being set at the time of our visit. On the Superior, development is progressing steadily, as heretofore. The incline has reached a depth of 300 feet, and a station has been excavated preparatory to drifting. The output of ore from the 200 level is just about the same as for the past six months, or about a car per week of the shipping grade.

BLACK RANGE NOTES.—*Lake Valley Herald*, Jan. 16: First-class miners are in demand in the Range. The last of the concentrator machinery is on the ground. The owners of the White Signal are getting out concentrating ores. Brad Williams, Superintendent of the Ivanhoe mine, has gone East to confer with the new owner of the property as to the best policy to pursue regarding it. The people of Grafton live in hopes that some work will be done upon it now and its present evil reputation contradicted. The Ivanhoe mine, sold at Sheriff's sale last month, brought \$3,200. The sale was made to J.

D. Brooks for J. B. Allee, of Boston, who held a deed of trust on the property for \$50,000, which was given to raise funds for working.

STRIKE.—A large and rich strike was made a few days ago in the Cincinnati mine in Tres Hermanas district. This mine is shipping ore to Socorro and Benson, and the owners are realizing handsomely therefrom.

ROYAL ARCH.—Rush Rowe, of Grafton, is in the city, and reports the Royal Arch mine down 225 ft., and showing a two-foot pay streak which will average \$30 a ton. The concentrator at Chloride will start in about sixty days.

OREGON.

NOTES.—*Jacksonville Times*, Jan. 18: Miners looking blue. Curtis Bros. have everything in good shape for effective work on Jackson creek. Quite a number of prospectors, some of whom had from California, are prospecting in Blackwell district. Capt. Kelley, having been put in possession of the Cayote creek mines, will commence active operations as soon as the cold weather is over. Wm. Clark, of Alt-house, Josephine county, whose claim has yielded a number of large chunks of gold, picked up a \$25 slug the other day. The prevailing weather is quite unfavorable for the miners, who are able to do little, if anything. It is hoped that the cold snap will speedily come to an end and give them a show.

UTAH.

STRIKE IN SILVER MOUNTAIN.—*Salt Lake Tribune*, Jan. 19: A letter has been received from the foreman of the Silver Mountain mine, which confirms the report brought by a miner a few days ago, of the discovery of a new ore body. The strike is the most important yet made, and the ore is of even better quality than any yet found in the mine. No ore can be hauled at present, but when regular shipments are begun in the spring there is every reason to expect that the mine will take rank as one of the foremost of our ore producers.

FRISCO.—*Southern Utah Times*, Jan. 19: The Carry Lode mining property is situated near Lober's Canyon about a mile and a half from town. The vein is a true fissure in a limestone formation. The main working shaft is now down to a depth of 40 ft., and follows the ledge, which dips west at an angle of 45 deg, from the perpendicular. The ore is a vein of clean ore running through the ledge, which has an average width of 12 inches. A drift is being run into the ledge at the bottom of the shaft, which is now in a distance of ten ft., exposing a fine body of ore. The ore is carbonate mixed with chloride of silver, and assays 70 ounces of silver and trace of gold. The ledge can be traced on the surface for a distance of several hundred ft. The *Record* man of Beaver visited the famous Cave mine the other day, and was much gratified at seeing the many evidence of improvement there. Among the many changes is the 500-foot tramway and the magnificent new hoisting works, machinery for which is now all on the ground. The large sum of money invested in this machinery, etc., shows that the owners of the Cave mine have faith in the permanency and profitable nature of their property, and well they might have, for it is truly a bonanza. Godbe, Chambers & Co. are pushing work on the Summit mine, which they have bonded from Guio and others. Taking Bradshaw district as a whole, it is pretty safe to assert that there is an exceedingly bright future in store for it. While the neighboring district of Lincoln has a somewhat unenviable name for tardiness, yet it is now looming up, the Croft brothers, especially, showing some exceedingly fine developments in their several mining properties. They are running both a night and day force of men, and I am informed, have already expended some \$10,000 in development with encouraging results. Success to them and all others who are developing the country. These mining camps will, and I might say, are giving Minersville a market for all its surplus farming products.

STAR DISTRICT.—*Southern Utah Times*, Jan. 13: Star district, the monarch mineral bearing belt of Beaver county, is a low and somewhat isolated range, situated five miles southwest of Milford, and about nine miles southeast of Frisco. The range is seven miles long and three miles wide. The trend is north and south. The formation is limestone and quartzite, resting on granite at an angle of 45 deg. The limestone is of the carboniferous age, while the quartzite to the west is silurian. It is remarkable, even in a rich mineral country, for the number of outcrops and the plentiful distribution of ores all over the district. Up to the present date it has produced about 1,000,000 tons. For the last five years it has taken a back seat as far as the production of bullion is concerned, but not so as regards prospecting. More cutting is being done to-day in Star district than in all the rest of Beaver county. The results are necessarily slow on account of the number of mines, the scattered territory and the amount of men never exceeding 25 or 30, but they are veterans, grizzled and wrinkled in their long and protracted struggle to bring out the district. At the present writing the camp never looked more favorable, there being not a vacant piece of mineral ground in the district. The Wild Bill and Flora has shipped 1,000 tons of ore. The Stalwart is patented. The Talisman shows 1200 ft. of cutting in shafts, drifts and tunnel. Among the other mines are the Uranus, Boston, Kanarra, a true fissure vein, shipped 120 tons of ore last year, Harrisburg, Mountaineer, Kemple, Monitor, Bismarck, St. Mary's, Waukegan, Big Bonanza, Creedmoor and the Magnolia, which shipped 50 tons of 40 ounce ore last month. The Wasco 850 ft deep, is also one of the good properties of the district, that will, before long, make itself known to the outside world.

Bullion Shipments.

Hinaver, Jan. 16th, \$2,342; Crescent, 16th, \$2,450; Ontario, 16th, 8,426; Horn Silver, 16th, \$6,000; Ontario, 17th, \$4,080; Horn Silver, 17th, \$6,000; Hinaver, 17th, \$2,440; Stormont, 17th, \$3,364; Ontario, 18th, \$4,185; Horn Silver, 18th, \$6,000; Ontario, 19th, \$4,151; Horn Silver, 19th, \$9,000; Syndicate, 14th, \$6,792; Navajo, 21st, \$7,000; Belmont, 15th, \$2,362; Contention, 19th, \$17,549.

For Mining Shareholder's Directory, Stock Reports etc., see page 80.

Mining Assessments in 1883.

So far as advised, 148 mining assessments became delinquent at the offices of the respective organizations during the year 1883. The list covers the dependent mines in California, Nevada and Arizona, besides a few in outlying Territories. The mines are as follows:

Mines.	No.	Amount.
Alaska	2	\$14,000
Alexander	1	50,000
Alhambra	1	7,000
Alpha Hydraulic	1	3,000
Alhion Consolidated	3	169,000
Alta	3	81,000
Andes	3	75,000
Argenty	3	80,000
Athletic Consolidated	1	5,000
Baker Divide	1	2,000
Bald Mountain	1	3,000
Bechtel Consolidated	1	26,000
Belcher	1	7,500
Belmont	1	100,800
Best & Belcher	1	32,400
Benton Consolidated	3	25,000
Belle Isle	1	25,000
Bodie Consolidated	2	100,000
Bodie Tunnel	1	40,000
Boston Consolidated	1	25,000
Bryant	1	750
Bullion	2	40,000
Calaveras	1	500
Caledonia Gold	1	10,000
Caledonia Silver	1	20,000
California	3	324,000
Cariboca	1	10,000
Campo Seco Copper	2	15,000
Challenge	1	50,000
Champion	1	9,000
Christy	1	12,000
Chollar	2	168,000
Columbus Consolidated	1	25,000
Confidence	1	6,240
Commonwealth Consolidated	1	2,500
Consolidated Anador	3	45,000
Consolidated Imperial	2	50,000
Consolidated Pacific	1	9,000
Consolidated Reforma Lead	1	4,500
Consolidated Virginia	1	108,000
Car	1	500
Day	2	60,000
Detroit Copper	1	5,000
Double Standard	1	5,000
East Mount Diablo	1	5,000
El Dorado	3	15,000
El Dorado Gravel	1	5,000
Elko Consolidated	2	30,000
Equitable Tunnel	1	10,000
Eureka Consolidated	4	200,000
Eureka Smelting	1	3,000
Eureka Tunnel	1	50,000
Excelsior	1	20,000
Excelsior Deep Gravel	2	32,500
Excelsior Water and Mining	2	25,000
Fair Villa	1	10,000
Fresno Enterprise	1	10,000
General Miller	1	1,000
Genesee Valley	1	4,000
Germania Lead	2	30,000

White Awake Prospecting	1	25,000
Whitethrop	1	8,000
Yankee	2	10,000
Young America South	1	10,000

We do not assume that the above assessment

money has all been collected, for in some cases we know there was an utter failure to collect a dollar, and in many other cases only partial collections are understood to have been made. Here is an instance in point where there was no money collected. The Noonday, North Noonday and Red Cloud Consolidated mines in Mono county, California, were heavily handicapped with debt upwards of a year ago. The Noonday mines had produced considerable bullion, but not enough to pay expenses of production and development. Each of these three mines, feeling it was a case of life or death with them, levied an assessment of \$100,000 last January. We understand that not a dollar of that \$300,000 was ever collected. The mines and property connected therewith were subsequently sold by the Sheriff, and bought in for account of the creditors. We believe nothing has been done with them since the sale. How much of the \$75,000 called for by the Tip Top mine in Arizona was ever collected we do not know, but it has been stated that the stockholders have abandoned the mine to the creditors. The Alhion Consolidated and Martin White mines in Nevada have collected but little of the amounts called for during the year.

It is quite probable that many other mines have had equally poor luck in collecting all the assessment money called for. Especially is this true of mines lying in the less important districts. We hazard little in saying that the amount of money paid in for account of assessments this year is the smallest in many years. Stockholders have become weary of these claims, especially as the mines have not been as remunerative as in former years. But for the element of stock gambling, it would be still more difficult to collect assessments. Most of the money called for is from the mines that are listed at the Boards. The large operators in these stocks manage to make enough out of the fluctuations in value to pay whatever assessments they are obliged to, and gather in the remainder from those who hope to become millionaires, but who are as far from the realization of their hopes as when they commenced. Mining is a legitimate and praiseworthy industry when prosecuted for what it is worth and on business principles. Divested of the assessment feature, there would be little inducement for turns in stock, and more concern for the legitimate development of ore bodies. The assessments delinquent this year have been apportioned among the following localities:

CALIFORNIA.			
Counties.	Amount.	Counties.	Amount.
Anador	\$45,000	Placer	\$104,774
Butte	22,000	Plumas	5,000

Sinaloa			25,000
Sonora			18,000

Silver King.

The most famous of Arizona's mines is probably the Silver King. This mine is in Pinal county, and the deposit was first casually discovered by a soldier named Sullivan, then under the command of General Stoneman, now Governor of California. Sullivan never utilized his discovery, and after his discharge from the army disappeared, and was supposed to have been killed by the Indians. Subsequently a party of five set out to find the locality from which Sullivan had obtained the nuggets. They were attacked by the Indians and one of the number killed. The discovery was made by the other four and properly located. After the mine had been opened Sullivan one day appeared as an applicant for work, and was employed. He had lost the chance of making the location for himself.

The four original owners of the mine were Charles C. Mason, Isaac Copeland, Benjamin W. Reagan and William H. Long. Mason and Reagan subsequently bought out their partners; and then Mason sold his one-half interest to James M. Barney. The company was incorporated on the 5th of May, 1877, under the laws of California. The early history of the corporation was attended with the usual obstacles of mining in a new district, distant from supplies. But as soon as matters began to run smoothly dividends were declared. The first dividend was paid in November, 1877, at the rate of fifty cents per share. These were kept up until the following June, when they were interrupted for

three months, after which two more were paid at the same rate. For the next two years our record shows no dividends. However, they were resumed in October, 1880, at the rate of twenty-five cents per share. These were kept up until last July, and again resumed in December. The record of Silver King dividends to January 1, 1884, is as follows:

1877	2	\$100,000
1878	7	350,000
1880	2	75,000
1881	12	300,000
1882	12	300,000
1883	7	175,000
Totals.	43	\$1,300,000

The year 1883 gives but little to report in addition to those preceding it. There has been no change in the mine, mill or management, excepting in the various details of the work from day to day. The main vertical shaft has been sunk something over another hundred feet, and a station put in 100 feet below the 714 level. This level has given most of the ore extracted and reduced the past year, and still continues to do so. The proposed improvements spoken of one year ago have all been completed and are in use. At the mill an artesian well was put down as an experiment and proved successful. The principal proposed additions to the plant the present year are, the introduction of the electric light at the mine above and below and at the mill, air compressors with power drills, including one diamond drill, at the mine, and the sinking of artesian wells at the mill. The suspension of dividends for five months of the year is attributable to short water at mill, bad air and lights during the heated term in the mine, and unusual but necessary expenditures of money in securing claims adjoining, settling of various lawsuits and securing title to property.

The amount of ore crushed at the mill during the year was 22,682 tons, yielding 67 shipments of concentrations of a little over 11 tons each, and aggregating 758 387-2000 tons. Thus, the ore shipped weighed 3 34-100 per cent. of that crushed. The average assay value of the ore as per daily assay was \$42.90, and that of the tailings, which can be determined pretty accurately on account of the presence of little or no native metal, was \$4.89. 2,390 tons of ore are now in reserve in the mill yards. The mine produced \$600,000, and divided among the stockholders \$175,000 in seven dividends of \$25,000 each during the year 1883.

The Cœur d'Alene Country.

Prior to June, 1882, no prospector had penetrated the wilds of the Cœur d'Alene country. In the month and year named, Messrs Gillet and Pritchard discovered a paying property. This first paying claim is now known as the Wyant, Peters, and Price, from the names of the owners. It is located on Pritchard creek, and it was from this claim that a nugget weighing seven ounces, which, devoid of impurities, is valued at \$110, was obtained. The height of the mountains above the basin is about 600 feet. The width of the gulch is about 50 rods, or 800 feet. The fall or dip of the basin is from one and a half to two inches to the rod. The altitude of the district is much less than is generally supposed, and a great deal less than almost any of the hitherto great camps. The altitude above the sea of Lake Pen d'Oreille is 2,000 feet; that of Rathdrum, 2,250 feet; and of Eagle city only 2,300 feet. Cœur d'Alene city has an altitude of about 2,000 feet, the same as Lake Pen d'Oreille. Snow usually commences to fall in the vicinity of Eagle city about November 1st, and continues until the first of April. Work will be resumed April 1st, and continue till the fifteenth of May, when the freshets, incident to the melting snows, will put a stop to mining for a month more. It is liable to be pretty wet. Last season an immense amount of water came down from the hills into the gulches, swelling Pritchard and Eagle creeks into broad and very rapid rivers. People would do well to bear in mind that the area of the district named, which has a length of ten miles, is all that has been materially prospected. The other is not yet sufficiently prospected to enable men to know of its character.

There has been some discussion as to the legal right of miners in the district to hold, under the old regime, 20 acres as a claim. Some have inclined to the belief that under late mining enactments, such claims could not lawfully hold, that in the spring when the throng sets in to the mines, these claims must necessarily be cut down. On this subject Captain Wooden of Eagle City, on being interviewed by a *Telegram* reporter said: "I understand the present United States mining laws to allow a miner, who complies with the usual requirements of location and development, to hold a placer claim of 20 acres. The territorial statute of Idaho and the regulations of the district admit of it. I understand them to be entirely in accord, and I am certain that every effort will be made by present property holders, should there be any dispute in the spring, to hold their claims intact at whatever cost. They went in early and endured much, and they will not relinquish their property in whole or in part, cost what it may. The 200 or more miners now there would quickly resort to arms were any attempt made to infringe upon the locations already made. Should there be any attempts to coerce them under a later regime bloodshed will be the result."

Consolidated Virginia Mines.

No work has been done in the C. and C. shaft during the past year, except necessary repairs. The pumping and hoisting machinery is in good order. The old Con. Virginia shaft continues to be one of the main up-cast shafts for the north end group of mines. In September last a chamber for a joint California winze, No. 2, was cut out, and a winze started down at a point in the joint California east drift 360 feet east of the joint winze down from the 2500. This winze will be sunk to the 2900 level, and connected with the main California south lateral drift on that level, forming a much needed air-way and taking natural ventilation down to that point. As to the 1500, 1550, 1650, 1750 and 1950 levels, it has not been considered safe to attempt the reopening yet, there still being indications of the existence of fire in the old stopes. The Secretary's report shows the receipts to have been as follows:

From assessment No. 19, \$107,707.40; assay office (Virginia), \$873.80; suction fan (Virginia), \$9.50; outstanding last annual meeting, since settled, \$97,168.23; proceeds settlement of bullion worked on joint account with other mines, fiscal year 1881, \$8,455.56.

The disbursements were: Nevada Bank, balance on hand, \$36,643.76; cash in San Francisco office, \$216.35; W. H. Patton, Superintendent, cash in Virginia office, \$1,659.25; Virginia office, \$594.74; hauling, \$68.77; books and stationery, \$291.75; advertising, \$504; water, \$50; hoisting, \$2,619.15; taxes, \$1,500.87; compressed air, \$17,533.52; bullion discount, \$159.93; interest and exchange, \$882.48; legal expense, \$2,324.75; California and Consolidated Virginia shaft, \$79,950; supplies, \$14,293.43; salaries and wages, \$51,103.44; expenses (San Francisco office), \$3,798.30. It will be seen that no bullion was produced during the year. The management has very evidently been economical.

Telephones in Mines.

During a recent mining exhibition in Europe the practical application of the telephone to mining was so undeniably proved that the committee gave the highest award of the exhibition to the company exhibiting the instruments. At two mines where they are using telephones satisfaction is being given. One of them has had six underground levels connected with the shaft surface; thus signals for the rise and descent of the skip, etc., may be given from any level, and should occasion require a signal may be given to the surface indicating that someone desires to speak. This is immediately answered, the conversation is carried on, and where previously two hours elapsed before a reply could be received at the bottom level it is now accomplished in as many minutes. For instance, supposing a miner has received an injury at the 215 level, a companion at once goes to the telephone, which is encased in a water-tight box, gives the signal for conversation, is immediately answered, and communicates to the captain at the surface the details of the accident, and asking for the skip to be sent to the level he names. The injured miner, whose life may depend upon speedy assistance being rendered, may thus be at the surface in ten minutes from the moment of the accident. In various other ways can the telephone prove its great utility to mining purposes, avoiding the repeated inconvenience of the failure of the "knocker line." In Wheel Agar the 125, 115 and 105 levels are brought to one set of apparatus at the surface, and the 195, 180 and 120 levels to a second set, thus allowing any two levels to communicate at the same time. At South Frances two shafts are fitted with telephonic communication; one shaft includes the 120 and 150 levels with the surface, the remaining shaft the 185 and 230 levels. In each mine the Blake and Bell instruments are used. These instruments have been specially fitted for the purpose.

MINING AT LEADVILLE, COLORADO.—In consequence of the heavy decline in lead during the last quarter, the mines of Leadville have not given the grand total anticipated; yet the exhibit is, nevertheless, extremely favorable when all the adverse causes are considered. For example, the Harrison Reduction Works with four furnaces were idle three months, owing to their destruction by fire and inability to procure sufficient ores. The La Plata smelter remained unproductive two months by the rebuilding of its plaus; the Leadville stamp mill lost two months, the Elgin smelter five, the Tahor mill seven, and the Shields seven months. Meanwhile millions of dollars' worth of ore accumulated; some was shipped out, and a large part remained unused. It must be remembered also that the Grant works here and the two large smelting concerns at Pueblo have from 10,000 to 30,000 tons of ore from Leadville which have no part in any of the statements for this year, and which, if converted into bullion, would raise the product of that district to a very much higher total than has been given. Taken all in all the exhibit is the most favorable ever made for the Colorado mines, and is as accurate as great care exercised in the compilation can make it.

THE ENGINEER.

Military Experiments in Snow.

A party of officers have ingeniously utilized snow in order to observe the effect of long-range firing. They selected a flat piece of ground upon the flanks of the Mont de Baumer, covered with snow, upon which they marked out a rectangle 230x98½ feet, representing a battalion in double column. In the middle of this they planted two flags. The artillery were placed at a distance of 1,748 yards, at an elevation of 282 feet above the target. Six officers then fired 300 rounds, aiming one-third at the central flag and the other two-thirds more to the left, in order to make allowance for the high wind then blowing. The snow showed clearly where each shot had struck, and in this manner it appeared that 78 per cent of the projectiles had fallen within the *enrante*. An experiment of a different kind was made to calculate the resistance opposed by snow fortifications to cannon shot. A wall was erected 16½ feet long and 5 feet high; the back was formed of one-half inch planking, and the front of snow in varying thicknesses. It was divided into three distinct sections, in the first of which the snow was 4½ feet thick, in the second 3 feet 3 inches, and in the third 20 inches in depth. Twelve shots were fired against the first section, at ranges of 246, 328 and 437 yards, but none of them traversed it. Shots fired from distances of 246 and 328 yards pierced the snow of the second section, but were stopped by the planking. All the shots pierced the third and thinnest section. Shots fired from 1,200 and 1,300 yards only penetrated the snow for a depth of from 15 to 18 inches.

A GUNBOAT APPROPRIATELY NAMED.—There is in the English navy a gunboat named the *Frolic*, the ways of which are so frolicsome and free, and which is afflicted with such a constitutional "bias" toward the star-board tack that one set of engines is required to develop 100-horse power more than the other to keep her in a straight line. The eccentricity is inconvenient, but totally inexplicable. Her propellers are of the same type, the screws of the same pitch, and the blades in perfect accord. Ordered to the Cape, her commander found himself going direct for New York, and concluded to put into Portsmouth before he got any further on the way. Now, had it been the *Polypemus*, one could have understood it, but for a respectable boat, blessed with a pair of everything necessary to keep her in a straight path, to exhibit such a rakish preference for devious courses, suggests truly painful explanations.

AN INGENIOUS DESIGN FOR AN EXPLORING STEAMER.—A vessel of special and ingenious design is being prepared for Stanley's use in Africa. It will be propelled by a stern paddle-wheel, and the hull will be arranged in such a manner that it can be readily subdivided into a number of sections, each being floatable, and provided with fittings for receiving four large wheels. These wheels can be attached to each section while afloat, so that it can be drawn out of the water for transport overland without difficulty. Each of the subdivisions of the hull forms, when fitted with the wheels, a complete wagon in itself, capable of carrying the machinery of the steamer, merchandise, etc. It is to be completed the first of this year, and will be tested afloat under steam on the Thames.

A NOVEL SNOW PLOW ATTACHMENT.—There have been various methods resorted to for the purpose of cleaning the snow from railway tracks, such as using steam or hot water in connection with the snow plow. The latest departure, however, in this branch of railway engineering, appears to be the use of a combined snow plow and cannon, which is provided with a triple muzzle, so that when fired it will loosen the snow and allow of its removal by the plow. The mechanism of reloading and firing is under the control of the engineer, being operated entirely from the locomotive cab.

CAPT. EAD'S LATEST PROPOSITION.—Galveston is throwing up her hat in honor of Capt. Ead's answer to her committee's letter relating to her bar. The Captain says that if Congress will give him \$7,500,000 he will guarantee thirty feet of water, and maintain that depth for twenty years at a cost of less than \$100,000 a year. He proposes to give that city twenty-two feet of water within two years. A Texas newspaper says that with thirty feet of water on her bar Galveston will soon rank New York City.

THE CAPACITY OF PIPES is as the square of their diameters; if you double the diameter of a pipe you increase its capacity four times. A cubic foot of water weighs 62½ pounds, and contains 1,728 cubic inches, or 7½ gallons. Each nominal horse-power of boilers requires one cubic foot of water per hour. The ordinary speed to run a pump is 100 feet of piston per minute.

THE THAMES.—The Thames is about to have a second tunnel. The Severn resents the attempt at a tunnel by periodically flooding out and drowning the operators. The Mersey tunnel is rapidly becoming a fact, and the projectors of the Humber tunnel promise success.

USEFUL INFORMATION.

How to Boil Linseed Oil.

First be sure that you have the pure linseed oil. There is much sold as such manufactured out of peanuts. The test is simple. Nut oil has a sharp, acid taste, smells just like sour peanuts, is darker and thicker than the other oil, has a clinging tendency when rubbed on the finger, dries with a gloss even in priming coats, and is very much given to gumming up when sanded. Pure linseed oil has a bright amber color, runs freely, sparkles when flowing from the can, tastes smooth and mild, and has the smell of a flax seed poultice. When you are satisfied that you have the genuine oil, and wish to boil it thoroughly, first take, say about one-half pound of red lead and the same quantity of sugar of lead, put into five gallons of the oil, and place over a slow fire so as to boil evenly. Do not let your fire get either too hot or too low; keep an even temperature, if possible; coke or charcoal is preferable to either hard or soft stone coal. Avoid a wood fire, as, after the oil gets to boiling heat, a sudden flame shooting up might ignite the entire lot. Let it boil seven hours full; the red lead and sugar of lead will then become dark brown. Stir all the time while boiling slowly, and only one way; do not change the direction of the stroke or you will burn the oil, just as you would starch. After you have taken it from the fire, cover it up and let it stand to cool off, say over night. The sediment will settle; pour out the oil and strain; your oil is boiled, and a better article you could not have, as all the fatty substances are destroyed. This is the English method, used in all the carriage factories in the United Kingdom.—*U. S. Carriage Monthly*.

REMOVING SPOTS FROM GILT FRAMES.—Gilt frames are liable to become spotted and look bad, while it is, as a rule, difficult to remove the spots. Rubbing does not answer, for the stain sticks tighter than the gilding itself, and washing is liable to loosen the gilt, if put on with gum or dextrine.

The *Papier Zeitung* recommends the following method of renovating gilt frames: It consists in applying with a camel-hair pencil a gum solution, to which has been added gold bronze having the color of the frame. Before mixing with the gum water the bronze must be washed with water till it runs off perfectly clear. If one application does not suffice it may be repeated until the spot entirely disappears; but of course one coat must be dry before the next is applied.

Spots treated in this way look very well at first, but it will not last, for it is not able to resist the moisture in the air unless it is specially prepared. For this purpose an ordinary bristle brush is rubbed with a piece of yellow wax until it is somewhat sticky; then it is passed very lightly over the spot several times, as when dusting it. This gives it a very thin coating of wax that hardens in two or three days; in the meantime it must be protected against dust.

A NOVEL ELECTRIC GAS LIGHTER.—The covered street at Milan, now well known as the Victor Emmanuel Gallery, is roofed with glass and completed by a large dome, round the interior of which runs a chain of gas lamps. The lighting of these lamps at a considerable elevation used to present some difficulties, and was always a source of risk, until an arrangement was made for doing the work by electricity. A miniature railway has been constructed close to the gas burners, on which runs a little electric locomotive carrying a wick steeped in spirits of wine. When it is desired to light the burners, this wick is set on fire and the locomotive started on its career. It flies round, rapidly kindling the circle, and exciting great interest among the crowds that assemble nightly to witness the performance.

TO CURE sheep skins for home use, with or without the wool, and to prepare sheep skins and cattle hides for market: If the skins are green, lay the skin flesh up, and spread equal parts of salt, saltpeter and alum, pulverized finely; roll the skins closely and let them lie for a few days. Then wash thoroughly and scrape off any flesh that may remain on the skin. Then soak the skins for twenty-four hours in a weak solution of sal soda, borax and soap. Then wash in soap suds and soak again in a weak solution of alum and salt, equal parts. Then wash in warm water and dry. Then work the skin to soften by rolling and rubbing. The raw skins of sheep and cattle need only salting and drying for market.

TO STRAIGHTEN A BAND SAW.—A correspondent of the *Scientific American* says: Put the saw on to the machine and under tension, just as it is to be used. Use a steel straight edge ten or twelve inches in length to find the lumps or twists, which mark with chalk so as to know where to hammer. Now hold the oval face of a millwright's or carpenter's hard wood mallet opposite the chalk marks and against the saw, and with a light, oval-faced hand hammer knock out the lumps. Commence carefully, do not strike too hard. Examine your saw often with your straight edge to see how you get along, and you will soon be able to take out twists readily and get your saw perfectly true.

GREAT INDUSTRIAL RIVALS.—Germany is an important rival of the United States in some

respects. Germany's population is six millions less than that of the United States, and six millions more than that of France. Germany has 7,000,000 workmen, or about half as many as the United States, and 5,000,000 horse-power, much less in this respect than ours, but this difference may be partially offset by the former's system of cheap labor. France has about 1,000,000 horse-power, but this amount is subjected to the greatest degree of economy, as only the French people know how to economize in large things as well as in small things.

COURT PLASTER.—Soak isinglass in a little warm water for seventy-four hours; then evaporate nearly all the water by gentle heat; dissolve the residue in a little dilute alcohol, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cold. Now stretch a piece of silk or sarcenet on a wooden frame, and fix it tight with tacks or pack thread. Melt the jelly and apply it to the silk thinly and evenly with a ladger-hair brush. A second coating must be applied when the first has dried. When both are dry apply over the whole surface two or three coatings of balsam of Peru. Plaster thus made is very pliable, and never breaks.

IMITATION WALNUT.—We have it on good authority, says an exchange, that an excellent stain for giving light colored wood the appearance of black walnut may be made and applied as follows: Take Brunswick black, thin down with turpentine until it is about the right tone and color, and then add about one-twentieth its bulk of varnish. This mixture, it is said, will dry hard and take varnish well.

IN HARDENING any article of steel that is thin or light and heats quickly, it is advisable to remove on a grindstone or emery wheel the scale formed in forging before heating. The scale being of unequal density, if it is not removed it is generally impossible to heat evenly; besides, the degree of heat can be better observed if it is removed.

TO WHITEN BRASS OR COPPER.—To whiten small articles made of brass or copper, boil them in three-quarters of a pound of cream tartar and one pound grain tin, or any pure tin finely divided. The tin dissolves in the cream of tartar and is precipitated on the brass or copper.

THE ORGAN INDUSTRY.—It is said that a single firm at Washington, N. J., has shipped 1,600 twenty-seven stop instruments during the month of November, 1883, against 980 for the same month of the previous year.

GOOD HEALTH.

Is Beer Healthful?

The belief that beer is a healthful drink is constantly urged upon us by manufacturers and lovers of this beverage, and physicians aid the spread of this delusion in many ways. It is not often that an unprejudiced person makes a careful study of the subject to see whether beer is really wholesome and life-giving or not, and so it is a pleasure to temperance advocates to hear from a man who has done so. That man is Colonel Green, President of the Connecticut Mutual Life Insurance Company. He says: "In one of our largest cities, containing a great population of beer drinkers, I had occasion to note the deaths among a large group of persons whose habits in their own eyes and in those of their friends and physicians were temperate; but they were habitual users of beer. When the observation began they were upon the average something under middle age, and they were, of course, selected lives. For two or three years there was nothing very remarkable to be noted among this group. Presently death began to strike it; and until it had dwindled to a fraction of its original proportions, the mortality in it was astounding in extent, and still more remarkable in the manifest identity of cause and mode. There was no mistaking it; the history was almost invariably: robust, apparent health, full muscles, a fair outside, increasing weight, florid faces; then a touch of cold, or a sniff of malaria, and instantly some acute disease with, almost invariably, typhoid symptoms, was in violent action, and 10 days or less ended it. It was as if the system had been kept fair outside while within it was eaten to a shell, and at the first touch of disease there was utter collapse; every fiber was poisoned and weak. And this, in its main features, varying, of course, in degree, has been my observation in beer drinking everywhere. It is peculiarly deceptive at first; it is thoroughly destructive at the last." This testimony is very strong, and we take pleasure in giving it to our readers, and we call special attention to the fact that a fair, ruddy outside is not always an indication of health, and also to the fact that, so far, the figures of the life insurance companies go to show that the teetotalers are likely to live longer than even the moderate drinker.

CHOOSE HEALTH OR SICKNESS.—Those who desire and appreciate health should be as willing to make some effort to secure it as they do to obtain the other good things which increase the pleasures of life. Pure water is essentially necessary to good health. All wells, cisterns and springs should be thoroughly cleaned in the early spring or in the autumn.

The usual method of placing a large stone on the top of the cistern is injurious to the water unless an aperture is left in the stone and fitted with a wooden cover. The air should not be wholly excluded from the cistern, else moldy conditions will predominate, although perhaps not apparent, and the water will not be wholesome, and in it sometimes there may be found various kinds of insects and reptiles. Water is the natural drink of all living creatures, and it serves several important purposes in the animal economy. Firstly, it repairs the loss of the aqueous part of the blood caused by evaporation and the action of the secreting and inhaling organs. Secondly, it is a solvent of various elementary substances, and therefore assists the stomach in digestion, though if taken in very large quantities it may have an opposite effect by diluting the gastric juice. Thirdly, it is a nutritive agent, that is, it assists in the formation of the solid parts of the body.—*London Lancet*.

DRINKING MILK. A correspondent of the *Herald of Health* asks: What is the best way to use milk when it seems best to increase the amount used? To which that paper answers: Persons who wish to introduce milk more largely into their diet to take the place of meat, will do well to make one entire meal of a day of milk, with oat-meal, wheaten grits, whole-lobbed wheat, rice, corn, or Graham mush, or bread. Although milk is as drinkable as water, it should be taken as food instead of drink, so as to receive the action of the salivary glands upon it, which forms a very important part in digestion. The value of milk as food cannot well be over-estimated, and the different ways in which it can be used are almost without number. Any one really desirous of making the most of it can quickly learn the number of delicious soups, puddings and vegetable dishes that can be prepared largely of it. Indeed, with milk, eggs, and fresh vegetables, which every farmer should have, not only in abundance, but variety, one can live most healthfully and deliciously. Those who use milk, however, should be sure it comes from healthy cows, and that it is not contaminated with bad water. We know a gentleman who takes for his breakfast every morning a fresh egg or two stirred into a glass of new milk, and he attributes to this, very largely, his remarkable health.

COLDS.—Young children are very subject to colds, for several reasons. First, their skins are unusually active and vascular, containing a much larger proportion of blood than those of adults; second, they are usually improperly clad, the middle portion of their body being so clothed as to induce perspiration, while the arms and legs are left nearly bare; third, they are rendered susceptible to cold air or drafts by being kept in too warm an atmosphere, and not exposed to out-of-door air. The habit of breathing through the mouth, which children are very apt to contract, may also be regarded as a frequent cause of taking cold, especially during the winter months. Children should be taught to inhale through the nose, the natural channel for inspired air, as by passing over the large mucous surface the air is warmed before entering the lungs, thus preventing congestion, which might give rise to serious inflammation of the air passages, or to pneumonia.

COCONUTS AS FOOD.—The coconut has a great sustaining power. A good instance of this is found in the case of a vessel which sailed some years ago from San Francisco for Sydney, New South Wales, with 400 passengers. The voyage was long and tedious, and there was a deficiency of provisions. Landing at an island a large quantity of coconuts was obtained, and for eighty days, in that water-logged ship, the men, women and children lived exclusively on them; and yet, during the voyage, not a life had been lost or a case of sickness occurred, but all were in excellent health. Another case is that of two men who drifted out to Quair's island in a whale boat, and remained there for seven years with no food but coconuts, and now and then a flying-fish which chanced to fall on the land, and yet when rescued they were in excellent condition, and had gained in weight.

WHICH IS THE BEST BEAN FOR FOOD.—*Herald of Health* answers this question as follows: The Lima bean is the best; but other kinds are also excellent, and it is just as well to use a variety of sorts. Another excellent bean is Carter's Leviathan Long Pod. The plant grows six feet high. Beans may be soaked in several ways, and ground to fine flour for soups. Bean soup is excellent, very nutritious and wholesome, and should appear on every table frequently.

RICE AND CORN.—Rice is rather more nourishing than corn in some respects and less in others. Rice has more albuminous and less mineral matter; corn more starch. It constitutes a chief article of food in India, where it costs about a cent a pound. As a food for children and invalids it ranks high, and is most easily digested, and does not cause indigestion. Its starch is almost all absorbed in the digestive tract, which is not the case with corn.

A NEGLECTED DISINFECTANT.—When the households of our grandmothers were threatened with infection the common practice was to sprinkle brimstone on a hot shovel, or on hot coals on a shovel, and carry the burning result through the house. But now this simple method of disinfecting has gone out of fashion without any good and sufficient reason.

TABLE OF CONTENTS.

EDITORIALS.—New Concentrator and Amalgama-
tor; The State Mining Bureau; A Railroad Inspection
Car, 69. Passing Events; Labor in Quicksilver Min-
ing; Silver Mining in California; Foundry Notes; Lime;
New Hydraulic Quick-boring Machine; California Mines,
76. Hydraulic Separator for Preparing Ores; Char-
acter of Mining Land; The Coming Rush, 77.
ILLUSTRATIONS.—A New Inspection Car for Rail-
road Use, 69. Hydraulic Separator to Prepare Ores
for Jigging, 77.
CORRESPONDENCE.—Tuscarora Mines; A Short
History of a Giant Quartz Claim; The Earth—Geo-
logical History, 70.
MECHANICAL PROGRESS.—The Limitations
of Machinery; Light Iron Castings; A Process for Soft-
ening Iron Castings; Effect of Furnace Gases on Iron;
The Spring Car Motor, Coke for Foundry Purposes, 71.
SCIENTIFIC PROGRESS.—San Diego Natural
History Society; The Fourth State of Matter; Dyeing
Cut Flowers; An Interesting Experiment; Bacteria in
Mountain Air, 71.
MINING SUMMARY.—From the various counties
of California, Nevada, Arizona, Idaho, Montana, New
Mexico, Oregon and Utah, 72-73.
THE ENGINEER.—Military Experiments in Snow;
A Gunboat Appropriately Named; An Ingenious De-
sign for an Exploring Steamer; A Novel Snow Plow
Attachment; Capt. Ead's Latest Proposition, 75.
USEFUL INFORMATION.—How to Boil Linseed
Oil; Removing Spots from Gilt Frames; A Novel Elec-
tric Gas Lighter; To Straighten a Band Saw; Great In-
dustrial Rivals; Court Plaster; Initiation Walnut; To
Whiten Brass or Copper; The Organ Industry, 76.
GOOD HEALTH.—Is Beer Healthful; Choose Health
or Sickness; Drinking Milk; Colds; Cocoanuts as Food;
Which is the Best Bean for Food; Rice and Corn;
A Neglected Disinfectant, 75.
MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Meetings, Assess-
ments, Dividends and Bullion Shipments, 80.
MISCELLANEOUS.—Recent Contributions to the
California State Mining Bureau, 70. Mining Assess-
ments in 1883; Silver King; The Cœur d'Alene Country;
Consolidated Virginia Mines; Telephones in Mines, 74.
As Was Expected; Academy of Sciences, 77.

Passing Events.

The end of the week has brought us the long
looked for and welcome rain which brings pros-
perity to all in California. With a good, steady
rain at this time a prosperous year is insured
for this State.

Note is made of the fact that some of the
hydraulic mining companies have discharged all
their ditch-tenders, and will let the ditches and
wasteways take care of themselves. The gates
of the dams have been opened, and the water
will be allowed to run to waste.

In the mining camps great interest is mani-
fested in all the news from the Cœur d'Alene
placers, in Idaho. There is no doubt but that
there will be a great rush for that region as
soon as the roads are opened.

Just now greater attention is being paid to
quartz mining in this State than for a long time
past.

The reports of rich placer diggings on Fish
creek, twenty miles from Butte, Montana, have
been confirmed. Gravel is ten feet deep, and
pays to the bed-rock.

Joe Bianchi and others will soon start up
the leaching works at Reveille district, Nevada,
on ores from the Gila mine. C. A. Ogden will
have charge of the works.

The Sutter Creek foundry is turning out a
large amount of work for the Pacific mine at
Plymouth, in order that the hoisting works
may be run by water and do away with wood.

Labor in Quicksilver Mining.

The quicksilver industry in this State cannot
be said to be in a flourishing condition. The
long prevailing depression in prices has had the
effect of closing down many producing mines,
and only the larger ones can now afford to work,
and they are not making much money for their
owners.

There are altogether about 1,200 men directly
employed in the quicksilver mines and furnaces
of California, in addition to whom a large num-
ber are occupied as wood-choppers, teamsters,
etc., working on contract. The leading national-
ities of the miners and furnace men may be
stated in the following order: Mexicans, Corn-
ishmen, Swedes and Chinese, with compara-
tively few Americans. The Mexican miners, as
in so many other instances, have developed a
special fitness for this class of work, and their
intelligence in finding ore amounts almost to an
instinct. For the regular underground work of
a mine, such as drilling, blasting, timbering,
etc., the Cornishmen and Americans probably
take the lead.

Miners at day work are paid from \$2 to \$3
per shift of 10 hours, and on contract work from
\$2.50 to \$3 per shift of 8 hours. The wages of
furnace men are \$2 to \$2.50 per shifts of 10 or
12 hours. The New Idria mine gives employ-
ment to about 120 men. There the wages of
white miners average \$2.25 cents per day, the
men hoarding themselves. Blacksmiths and
other mechanics and overseers are paid \$4 per
day. The Great Eastern mine employs 35 men,
half of whom are Chinese. At this mine white
miners are paid \$2.50 per day, hoarding them-
selves, and the Chinese, \$1.25. The Napa Con-
solidated employs from 60 to 70 men at about
the same wages. At the Sulphur Banks, when
at work, 90 men are employed, and the same
wages are paid as at the Great Eastern. In all
these mines mechanics and foreman are paid from
\$3.50 to \$4 per day. The Great Western gives
work to 25 men; white miners are paid \$1.25
per day and board; Mexicans \$2.50 and \$3
per day and board. At New Almaden, where a
force of 500 men is kept at work, the average
daily wages are \$2.50.

An estimate has recently been made from the
working results of different mines, showing that
for every flask of quicksilver produced nine
days' actual labor (calculated as if done by one
man) is required. This, at the low average of
\$2 per day, would make the amount paid for
labor \$18 for every flask manufactured, or be-
tween 23 and 24 cents a pound. This, at present
prices of quicksilver, does not allow much
margin for profit after accounting for the other
expenses, such as supplies, fuel, powder, flasks,
steel, transportation, etc.

Silver Mining in California.

After suffering a relapse and remaining under
a cloud for several years, this branch of mining
is again looking up in California, and the State
may even be expected to soon come to the front
as a producer of silver bullion. This view is
based on the large output of silver last year in
San Bernardino county, and the prospect that
the same will be materially increased the cur-
rent year. Without admitting the extravagant
claims advanced for these mines by the local
press off that way, there is no denying that
their record so far has been a good one, nor is
there much question but they will be able to
greatly augment their product hereafter. The
mineral territory is extensive, the metalliferous
veins are numerous, and the ore generally of
high grade. If now, the deposits prove perma-
nent, the future of these mines may be looked
upon as assured, the railroads that strike across
or near that country removing in part the great
impediment that heretofore checked the
development of its resources.

What railroads are doing for this eastern
section of San Bernardino, they are tending to
accomplish also for Alpine, Inyo and Mono
counties—our other leading silver producers—
where, also, mining for this metal has under-
gone much improvement of late. We hear of
some new smelters being erected in Inyo; also
of mills and reduction works doing an increased
business in that trans-Sierra tier of counties;
and, that there is greater activity in mining
over there than has prevailed for several years
past, seems evident.

SODA SPRINGS.—Williams, Bisbee & Co. are
arranging to start up the old copper smelter at
Soda Springs, in Esmeralda county, Nev.

Foundry Notes.

The Risdon Iron Works, which a short time
since completed the heavy hydraulic pumping
machinery for the Comstock, and which we de-
scribed at the time, has just shipped 15,000 feet
of 18-inch wrought-iron pipe to the Plymouth
mine, Amador county.

The Glohe Iron Works are quite busy on gen-
eral work, and are making a specialty of the
"Dyer Cannon Ball Quartz Mill," which we not
long since illustrated and described in the
PRESS. The machine is said to have proved
itself a cheap, effective and durable ore reduc-
ing appliance, and is no longer considered ex-
perimental. It has been thoroughly tested in
the mining regions, and the manufacturers say,
have met with unprecedented favor. A number
of mining superintendents who have been using
these mills testify to their efficiency.

The Union Iron Works are busily engaged on
their new and extensive plant near the Rolling
Mills, at the Potrero. The new works will have
as much capacity as all the foundries in the
city combined, and will be fitted with every
possible labor-saving appliance and convenience.
The various buildings are arranged in a manner
dictated by the long experience of the prop-
rietors, and are of a durable character. In the
matter of light and ventilation, things too often
partially neglected, these works will be notice-
able. The buildings have sides in which there
is a very large proportion of glass, so that the
interiors will be light and cheerful instead of
dark and gloomy, as is too often the case. The
new works will require a large outlay for their
completion, as they are of a very extensive char-
acter. New specialties are to be taken up,
among them iron shipwork, repairing, etc.
The works have a water frontage, and the de-
sign contemplates a wharf and dry dock. San
Francisco is one of the most extensive shipping
ports of the world, and the business is expected
to extend. The expense of docking and repair
has been a great drawback heretofore, but the
combination of iron works and dry dock is a new
feature, which should remove the objectionable
points. The enterprise of the gentlemen con-
nected with the company is greatly to be com-
mended. Doubtless it is one of the results of
Mr. Irving M. Scott's tour around the world,
for on his return he must have been even more
than ever impressed with the importance of this
city as a center for the manufacturing interest,
and have seen into the future far enough to feel
assured of its ultimate needs.

Lime.

Lime for mortar and other building purposes
is burnt to a greater or less extent in every
State in the Union. The production is esti-
mated to be about 31,000,000 barrels of 200
pounds each, worth 65 to 75 cents per barrel,
spot value. The total valuation of the product
is some \$21,700,000. The lime product presup-
poses the quarrying of about 6,000,000 tons of
limestone. In the Rocky mountain region lime-
stone occurs everywhere in great quantity and
purity, and kilns are erected where local de-
mands warrant it.

Common limestone, though an abundant rock
on this coast, occurs sparingly in Oregon, and
perhaps also in Washington Territory. The re-
ceipts of lime at San Francisco for the ten years
ending with Jan. 1, 1884, were as follows, the
whole being the product of California:

Years.	Barrels.
1874.....	145,213
1875.....	132,631
1876.....	174,758
1877.....	155,113
1878.....	144,072
1879.....	104,405
1880.....	133,097
1881.....	123,779
1882.....	133,306
1883.....	155,053

This year our production was greater than for
some time past. During the past ten years the
prices of lime in San Francisco have varied from
\$1.50 to \$1.75 per barrel, the present price being
from \$1.25 to \$1.50 per barrel. The price de-
pends somewhat on the quantity purchased, but
generally it has varied little during the year.
The lime business here is all in the hands of the
two firms, Davis & Cowell and Blochman & Cerf.
While lime is burned at various parts of the
State, about one-third of the California product
is made in Santa Cruz county, where a highly
crystalline limestone occurs in great abundance.

A PASSENGER and transportation company, to
run freight lines and stages between Spokane
Falls, W. T., and Cœur d'Alene, I. T., was
formed at Spokane Falls Saturday.

New Hydraulic Quick-Boring System.

The systems of deep earth boring by means
of the diamond crown offers many advantages,
but it has also some serious defects. Chief
among these is its unsuitability for soft, and es-
pecially gravelly strata. A thin bed of such a
character will seriously retard the progress of a
boring; in some instances it has been found to
be impossible with the diamond borer. The
substitution of the ordinary falling tools in such
cases takes up so much time and is so liable to
injure the bore-hole that the evil can hardly be
said to be obviated by this means. An inven-
tion of Olaf Terp for removing this defect from
the system has recently been tested in Austria,
and is now working very effectively at the col-
lieries of John D. Stark, at Prague. It con-
sists of a steel borer of a peculiar construction,
which is made to replace the diamond crown
when a soft stratum is encountered. Hydraulic
pressure is used in conjunction with this boring
tool to force up to surface as sludge the material
cut away at the bottom of the hole. This con-
stitutes the principal feature in Terp's system,
and hence the latter has been named "the hy-
draulic quick-boring system." It will be per-
ceived that the removal of the sludge by this
means not only keeps the drill edge clear, but
saves the great loss of time which would other-
wise be incurred in the frequent raising and
lowering of the tools. When the soft stratum
has been pierced and solid rock again reached
the diamond crown resumes the place of the
steel borer, and cores several inches in diameter,
and from fifteen to twenty feet in length, are
brought up. The speed with which the difficult
strata are passed through by this system justifies
its appellation of "quick-boring," and the
highly satisfactory results already attained have
attracted the attention of the well borers in the
petroleum districts, who are preparing to adopt
it. For prospecting purposes it is so admirably
suitable that its application is likely to be
widely extended.

California Mines.

California is not by any means going to drop
out of sight as a mining country; and even its
production of precious metals is not going to be
so very materially decreased as some persons
appear to imagine. Of course the cessation of
work on the hydraulic mines will have a serious
effect in more ways than one; but the stoppage
of those mines does not stop all the mining.
The drift owners will continue work, and some
parts of some of the hydraulic mines will be
drifted. And river-bed mining and silver min-
ing will both add up something to our bullion
product. Already a tendency is manifesting
itself, as the PRESS predicted, to an increased
attention in quartz mining. Men who can no
longer work in the hydraulic mines will hunt
up quartz mines and work them, either taking
up old claims or prospecting for new ones. In
fact there seems to have arisen as one of the re-
sults of the hydraulic mining litigation a sort
of quartz boom in several of our counties.
Greater interest is now taken in quartz mining
than for some time past; and there is reason to
believe this will spread. As evinced by our
very complete mining review published last
week, the PRESS has every confidence that Cal-
ifornia will continue to be a leading mining
State. So firmly established a business as min-
ing is among us is not likely to be entirely done
away with simply because a branch of it meets
with unfortunate reverses.

RUBY DUNDERBERG.—The day's-pay men
who were discharged from the Homo Ticket
mine, belonging to the Ruby-Dunderberg Min-
ing Company, were offered a chance to resume
their places and work for a percentage of the
net profit of all the ore extracted from the
mine. The terms did not suit the miners, so
they refused to work, and are still out.—*Eureka
Sentinel.*

A MILL is being built near the mouth of Cot-
tonwood, at the southern end of Fish Lake
valley. O. K. Berry and a number of other
miners in that district have mines which will
yield gold ore enough to keep the mill profitably
employed for years. So says the *Virginia En-
terprise.*

THE Nevada *Herald* learns that the Sailor
Flat mine, at Blue Tent, which is one of the
enjoined mines under the Sawyer decision, will
not attempt to drift, as has been stated, as it
would be impracticable, as the gold is found
widely scattered, and in very fine particles.

The Secretary read the following list of appointments by the Council for the year:

Publication Committee, George Davidson, Chas. G. Yale and Dr. H. H. Behr. Curators—Birds and mammals, E. F. Loring; radiates, reptiles and crustacea, J. J. Rivers; fishes, Miss Rosa Smith; ethnology and osteology, A. B. Stout; botany, E. L. Green and Mrs. Mary K. Curran; entomology, H. H. Behr; conchology, Josiah Keep; mineralogy, J. T. Evans and W. M. Wolfe; geology and paleontology, Melville Attwood.

Metallurgy and Ores.

Nevada Metallurgical Works.

NO. 28 STEVENSON STREET,
Near First and Market Streets, S. F.
[ESTABLISHED, 1869.]

C. A. LUCKHARDT.

B. SALAZAR.

Ores worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, etc.
Working Tests (practical) Made.
Plans and Specifications furnished for the most suitable Process for Working Ores.
Special attention paid to Examinations of Mines; Plans and Reports furnished.
C. A. LUCKHARDT & CO.,
(Formerly Huhn & Luckhardt),
Mining Engineers and Metallurgists.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

Assayers' Materials,
MINE AND MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, ETC.

118 and 120 Market Street and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the de-
mand for these goods, both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and val-
uable tables for computation of assays in grains and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

THE ROLLER ORE FEEDER.

[Patented May 23, 1882.]

This is the best and cheapest Ore Feeder now in use.
It has fewer parts, requires less power, is simpler in
adjustment than any other. Feeds coarse ore or soft
clay alike uniformly, under one or all the stamps in a
battery, as required.

In the Bunker Hill Mill it has run continuously for two
years, never having been out of order or costing a dollar
for repairs.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x30. This latter size furnished J. R. Huggin or Giant and Old Abe Co., Black also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Glossary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commission's Codification, and gives many an improved form. Price—Full law binding, extra paper, \$3.00.

For Sale by DEWEY & CO., San Francisco.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR, OR VANNER MACHINE.

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED and SEVENTY-FIVE DOLLARS (\$750.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanner Machine Company. That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements. That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanner Machine Co.,

Room 7—No. 109 California Street, January 3, 1884.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarrad Manila Rope, Hay Rope, Whale Line, etc., etc. Extra sizes and lengths made to order on short notice.

TUBBS & CO.,

611 and 613 Front St., San Francisco,

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252 Market St., S. F.]

FOR WEEK ENDING JANUARY 8, 1884.

- 291,567.—CAN OPENER—H. Benthall, S. F.
291,489.—PAPER BAG HOLDER—Albert Brown, Mendocino, Cal.
291,691.—SINGLE CABLE TRACK RAILWAY—J. J. Clisham, San Diego, Cal.
291,583.—MACHINE FOR HOOPING BARRELS—Duff & Allen, S. F.
291,585.—DIRT SCRAPER—Chas. Endicott, Kingsburg, Cal.
291,595.—WATER COOLER—W. A. Hawthorn, Hawthorn, Nev.
291,733.—ROAD CAR—H. Hortop, Rutherford, Cal.
291,526.—SECONDARY BATTERY—Molera & Cebrian, S. F.
291,627.—COMBINATION TOOL—John Ryan, Salt Lake City, U. T.
291,597.—WASHING SOAP—R. H. Withington, Sacramento, Cal.
291,836.—WINDOW SCREEN—Geo. W. Boynton West Oakland, Cal.

FOR WEEK ENDING JANUARY 15, 1884.

- 291,982.—BUTTON CARD—H. A. Buttner, San Quentin, Cal.
292,097.—SAW TOOTH SWAGE—S. J. Chalfant, Albion, Cal.
292,105.—LIFTING PUMP—Curtis & Caine, Logan City, U. T.
291,994.—FARM GATE—C. J. Doane, Gilroy, Cal.
291,597.—CONCENTRATOR AND AMALGAMATOR—Geo. N. Evans, S. F.
291,894.—JET WATER WHEEL—A. J. Gould, Quincy, Cal.
291,898.—CABLE RAILWAY PROPULSION—W. W. Hanscom, S. F.
291,921.—CARD FRAME—A. W. McArthur, Arroyo Grande, Cal.
292,025.—TRANSMITTING POWER—McCall & De Vry, S. F.
292,031.—CENTER BOARD—Mills & Gordon San Rafael, Cal.
292,034.—SECONDARY BATTERY—Molera & Cebrian, S. F.
292,036.—SAND BAND FOR WHEELS—M. Raphael, Wadsworth, Nev.
291,947.—IRRIGATING APPARATUS—C. M. Skillen, Pasadena, Cal.
291,956.—FASTENING FOR TOOL HANDLES—T. A. Sweet, Cambria, Cal.
292,080.—CANNING APPARATUS—R. Wheeler, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

ADJUSTABLE CENTER-BOARD FOR VESSELS.—George L. Mills and U. M. Gordon, San Rafael, Marin Co. No. 292,031. Dated Jan. 15, 1884. This center-board has a peculiar adjustability adapting it to maintain its perpendicularity. The center-board is hinged along its top longitudinally, and pivoted at one end; and means are provided for turning it laterally on its hinge. The object is to keep the board perpendicular, no matter what may be the list or heel of the boat, in order to prevent her falling off to leeward from lateral pressure of the wind. The operation of the device is as follows: When the boat has a list and a consequent tendency to "fall off" or slide to leeward, the center-board being lowered, would, in ordinary cases, have an inclination with the boat. In this case, however, by the movement of a wheel and suitable mechanism, the center-board is slanted at a suitable angle to be at right angles with the surface of the water, and may be kept in that position. As the vessel comes on the other tack, the inclination of the board may be reversed. Any desired angle may be maintained in accordance with the amount of list the vessel takes.

TRANSMITTING POWER FROM CENTRAL STATIONS.—Wm. McCall and J. V. De Vry, S. F. No. 292,025. Dated Jan. 15, 1884. This invention relates to a means for transmitting power from a central or distant source, and it consists of a flat traveling endless cable, having openings or eyes formed in it at regular distances apart. This cable is driven by fixed machinery at some point, and travels over pulleys which lead it to the point where the power is desired. Shafts extend from the buildings where the power is to be used, and have toothed wheels fixed to their outer ends, the teeth engaging in slots or openings in the cable, so as to be driven by it. The invention is applicable where street cable railways are laid, and the power being taken directly from the endless traveling cable which propels the cars; or the cable may be laid especially for the sole purpose of transmitting power.

CANNING APPARATUS.—Richard Wheeler, S. F. No. 292,080. Dated Jan. 15, 1884. This invention comprises an apparatus for putting up hermetically sealed goods of all descriptions, in which a reservoir and heater are employed with a series of separate inclosed chambers to contain the cans or jars and a means of supplying steam or hot air. The present invention consists in certain improvements in the chambers for retaining the jars or cans in a central position,

in a shield or means for protecting the operator from the escaping steam when the door of the apparatus is opened, and in an exterior double walled case having openings in valves, through which hot air may be admitted around the inner chambers, so as to partially superheat the steam.

SUPPORT FOR BEAMS AND GIRDERS.—Peter H. Jackson, S. F. No. 291,192. Dated Jan. 1, 1884. This invention relates to an improved connection and support between girders and beams which meet them at right angles and at points intermediate between their ends. It consists of independent wrought-iron plates which extend across the girder or girders, and also over the end of the beam, above and below, and a wrought-iron clamp or band which surrounds the end of the beam and the plates, together with bolts, wedges and check pieces. Mr. Jackson has made a specialty of the construction of beams, girders, etc., and has made several inventions in this line. As they are rapidly introduced into use they must be of a practical character, adoption being probably the best proof of this.

KEY-FASTENER.—E. W. Wagner, Cherokee, Butte Co. No. 291,434. Dated Jan. 1, 1884. The object of this key-fastener is to receive the key within the lock, in order to prevent it from being turned from the outside by those means in use by those who seek unlawful entrance. The invention consists of a sliding bolt seated within the lock-casing and operated by means of a thumb-piece projecting through a slot in said casing, said bolt being adapted to engage with a notch in the bit of the key.

If you want a lubricant that will run any thing cool write CHARLES J. WOODBURY, GENERAL MANAGER LUBRICATING DEPARTMENT CONTINENTAL OIL AND TRANS. CO. for "Lubric." It is the best compound-grease in the market. Shipped in 5, 10 and 25-pound cans, half barrels and barrels. Warranted to give satisfaction. Observe the numbers: No. 2 is soft for outside work; No. 3 is medium soft; No. 4 is medium hard; No. 5 is very hard, where unusual lubrication is demanded. Send for Catalogue of Lubricating Oils.

Mining Share Market.

The main interest has been in Bodie during the week. The Bodie Free Press says in relation to the matter, that "the new management has but little to say about the development, but the miners who quit when the change took place last Monday, can talk of nothing else. The town, in fact, has been in a fever of excitement over the strike for two weeks past, and everybody here believes the mine to be more valuable than it ever was before. The fact is recalled that on the strike of the first Bodie bonanza in 1878, the stock went to \$56 per share, and on the second in 1879 to \$45, they now look for something similar or even greater. There are between 23,000 and 24,000 shares of the company's stock in the treasury of the company in San Francisco, taken in from the last assessment; so the mine is now represented by between 76,000 and 77,000 shares only.

Up on the Comstock all work at the north end is progressing very satisfactorily, and they will now shortly have things in shape for doing some very interesting prospecting work at that end of the lode.

At the Gould and Curry, the old Bonner shaft has been put in good repair down to the 1,200 level. They will now clean out and repair the main north drift on that level up to the Consolidated Virginia line, when J. P. Jones will take the drift, and put his men into it. They will then advance into the ground in the California and Consolidated Virginia which is covered by the Jones contract, and will at once begin taking out and shipping ore.

At Gold Hill all operations are still on a small scale because of the low stage of water in the Carson river. Also, there has been some trouble on account of the wheels of the mills freezing up of nights. At the Alta they are now about ready to resume work in the face of the east drift, when they will push out to the ore body tapped by the diamond drill.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

A MACHINE to make bobnails with a capacity of one ton per day, has been invented at Pittsburg, where a factory will shortly be established. Three men can thus do the work formerly requiring one hundred.

DURING the year past \$631,166.77 in gold coin, dust and bullion have been shipped from the town of Pendleton, Or.

A TRAMP was recently found frozen to death on top of a sleeping car near Caliente.

MINING SHAREHOLDERS' DIRECTORY.

COMPILED EVERY THURSDAY FROM ADVERTISEMENTS IN MINING AND SCIENTIFIC PRESS AND OTHER S. F. JOURNALS.

TATUM & BOWEN,

25, 27, 29 and 31 Main St., near Market. SAN FRANCISCO.

and

187 Front Street. PORTLAND. OREGON.

SOLE AGENTS FOR

The Albany Lubricating
COMPOUND AND CUPS,
THE ALBANY CYLINDER OIL,
LARD OIL, WEST VIRGINIA LUBRICATING OIL, DOWNER'S MINERAL SPERM SKID OIL, ETC.

WE ALSO IMPORT

These Lubricants have been for the last eight years, and are now, in general use in nearly all the mills, mines and steamers on this Coast, and the fact that the demand constantly increases is sufficient evidence of their superiority.

MECHANICS' INSTITUTE INDUSTRIAL EXHIBITION

(Of the City of San Francisco.)

PREMIUMS AWARDED-1883.

GEORGE CUMMING & CO.,

— MANUFACTURERS OF —

Machine Tools, Hydraulic Machinery and PORTABLE FORGES,
18 & 20 Fell St., opp. cor. 10th and Market, San Francisco.

Awarded 1st Premium for Engine Lathe, and Special 1st Premium for Portable Forging

GOLD MEDAL AWARDED

— AT —
Mechanics' Fair, 1883,— FOR —
Automatic Cut-Off Engine.
SILVER MEDAL AWARDED— FOR —
Best Hoisting Engine and
Boiler Combined.

W. H. OHMEN,

Machine and
Engine Works,109 & 111 Beale St.,
SAN FRANCISCO.

WESTERN IRON WORKS,

BIGELOW, SIMS & MORRIS

— MANUFACTURERS OF —

CHAMPION METALLIC WHEELBARROWS.

First Premium, Mechanics' Fair, 1883.

We claim this Barrow to be superior to all others manufactured on this Coast. For railroad, mining, grading and general contractor's use, they stand without an equal. We guarantee them to stand more hard usage than any other Barrow yet manufactured. We solicit Correspondence.

123 & 125 Beale St., San Francisco.

IRON CASTINGS OF ALL DESCRIPTIONS.

GIANT POWDER,

MANUFACTURED UNDER ALFRED NOBEL'S Original and only valid Patents for NITRO-GLYCERINE Powders, which has been and still is of such immense advantage to the Miner, Railroad Man and the Engineer. All other Nitro-Glycerine Compounds are cheap imitations and adulterations of the Original Giant Powder. The GIANT POWDER COMPANY manufacture three grades of Powder, which are the Safest and Strongest High Explosives in the market. The Original Nitro-Glycerine Compound, GIANT POWDER or DYNAMITE, is acknowledged by all the great chemists of the world as unapproached by any other compound. The GIANT POWDER COMPANY have acquired the exclusive right to manufacture "NOBEL'S EXPLOSIVE GELATINE," which contains 96 per cent of Nitro-Glycerine. It is still stronger than Dynamite, and even safer in handling. This explosive was used in constructing the Mont Cenis Tunnel. THE JUDSON POWDER is a black Powder owned and Manufactured by the GIANT POWDER COMPANY; is from three to five times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it Breaks More Ground, Pulverizes Better, and Saves Time and Money. The only difficulty heretofore experienced by some consumers of this Powder has been that it required more time to get it to the bottom of a deep borehole. This has now been entirely overcome, and our JUDSON IMPROVED is now as dry as the ordinary Blasting Powder and runs as freely.

Triple, Quadruple and Quintuple Caps and all grades of Fuse for Sale.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending December 31, 1883, the Board of Directors of the German Savings and Loan Society has declared a dividend on Term Deposits at the rate of four and thirty-two one hundredths (4 32/100) per cent, per annum, and on Ordinary Deposits at the rate of three and six tenths (3 6/10) per cent, per annum, payable on and after the 2nd day of January, 1884. By order,
GEO. LETTE, Secretary.

CORRESPONDENCE is cordially solicited from reliable sources upon all topics of interest and value to our readers.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers. \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Licharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Onpellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Course Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 166 1/2 pages, with illustrations, well bound in cloth. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II. Gold and Silver; Part III. Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

DIVIDEND NOTICE.

OFFICE OF THE

Bulwer Consolidated Mining Company.

San Francisco, January 16, 1884.

At a meeting of the Board of Directors of the above named company, held on the 15th inst., Dividend No. 10, of ten cents (10c.) per share, was declared, payable on Thursday, January 31, 1884. Transfer books closed on Wednesday, January 23, 1884, at 3 o'clock p. m. This dividend is payable at the office in this city on all stock issued here and at the Farmers' Loan and Trust Company in New York on all stock issued there. WM. WILLIS, Sec'y.

OFFICE—Room 29, Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace
many features that are entirely new and of great practical
utility, which are covered by letters patent.

No other furnaces can compare with these for dura-
bility and in capacity for uninterrupted work.

MORE THAN ONE HUNDRED of them are now run-
ning on the Pacific Coast, giving results never before
obtained as regards continuous running, economy of
fuel, grade and quality of bullion produced. We are
prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requir-
ing no brick or stone work, except that for the crucible,
thus saving great expense and loss of time in construc-
tion.

Complete smelting plants made to order of any capacity
and with all the improvements that experience has sug-
gested as valuable in this class of machinery. Skilled and
experienced smelters furnished when desired to a upon
tend construction and running of furnaces. Estimates
given upon application. Send for circular.

and New York.

MINERS' HORSE WHIM.

ONE HORSE CAN EASILY HOIST OVER 1,000 LBS.
at a depth of 500 feet. The Whim is mainly built of
wrought iron. The hoisting-drum is thrown out of gear
by the lever, while the load is held in place with a brake
by the man tending the bucket. The standard of the
whim is bolted to bed-timbers, thus avoiding all frame-
work. When required, these whims are made in sections
to pack on mules.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

"Challenge" Ore Feeders.

OVER 1100 HAVE BEEN IN SUCCESSFUL OPERATION.

Awarded First Premiums at the Preceding and last Industrial Fairs of the Mechanics' Institute of San Francisco.

TWENTY PER CENT. MORE ORE CRUSHED WITH FIFTEEN PER CENT. LESS WEAR OF IRON THAN BY THE OLD METHOD OF HAND-FEEDING.

The opposite cut illustrates the recent introduction of a Spring Attachment, which replaces the Weight originally used, and results in an obvious improvement.

The practical operation of the large number of these machines now in use demonstrates the fact that the principle upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking table. Uniform feed is not possible upon the latter plan. The ore must be evenly carried upon a steady, advancing plane or table to the face or point of discharge, and there be simply dropped. Jerky or spasmodically acting contrivances will not answer the purpose for feeding wet or sticky ores, nor for the ores of mines where they may change from hard quartz to an intermixed material of quartz and clay matter.

These Feeders are in successful practical operation in the following Quartz Mills, and are giving perfect satisfaction to their Managers.

Gold Watch Free.

The publishers of the Capital City Home Guest, the well-known illustrated Literary and Family Magazine, make the following liberal offer for the New Year: The person telling us the longest verse in the Bible, before March 1st, will receive a Solid Gold, Lady's Hunting Cased Swiss Watch, worth \$50; If there be more than one correct answer, the second will receive an elegant Stem-winding Gentleman's Watch, the third, a key-winding English Watch. Each person must send 25 cts. with their answer, for which they will receive three months' subscription to the Home Guest, a 50-page illustrated New Year Book, a case of 25 articles that the ladies will appreciate, and paper containing names of winners. Address, Pubs. of HOME GUEST, HARTFORD, CONN.

Pacific Coast Clays.

Elsewhere we mention among the mineral products of California the various clays. While most of the discoveries of fire and fire-potters' clays so frequently announced have proved disappointment, the deposits, many of them being infusorial or other worthless earths, material suitable for fire-brick and earthenware really exists in many places on this coast, the following being the California localities most distinguished for these natural products: Steatite saponite or soapstone, a good fire clay, reported as occurring near Mokelumne Hill, Calaveras county; at the town of Antioch, in the claims of the Black Diamond mines, Contra Costa county; in the Como Grande mine, Inyo county; at Lincoln, Placer county, and at various places in El Dorado, Mendocino, Santa Barbara and Los Angeles counties.

Clay from some, if not all of these counties, has been made into fire-brick, crucibles, etc., and is found to answer well for these purposes. While some of the trials of California fire-clays have turned out badly, others have proved successful, and most of our fire-brick could be made at home. The price of the imported asked here ranges from \$35 to \$45 per thousand, that of domestic manufacture being about one-third less. A clay found in Brigham canyon, and at other points about Salt Lake, has been used extensively and with satisfactory results at the large smelters operating in Utah. A species of sandstone quarried in Red Butte canyon, near Salt Lake, has also been employed for building furnaces. Deposits of Kaolin have been found in this State, but have not been utilized as yet. Clays suitable for the manufacture of stoneware and the more common kinds of earthenware, are common on this coast, so there are several potteries in California, Oregon and Utah. The principal one in this State is at Lincoln, Placer county.

SOUTHERN PACIFIC.—Mr. John Hambleton, of Tulare City, who has just returned from the Needles, on the Colorado, writes that the new hotel and round house put up there by the railroad company are the finest buildings on the road. The Needles will be, he thinks, a mining center in time as there is a mineral country all round, on both sides of the mine. The scenery is beautiful along parts of the road. The road from Posie creek to Soledad will be started before long as the surveyors are at work on it now. Mr. Ambrose has said he shipped material out to Lardo. He says the road will start from that point and go through the Lawlers pass, south of the Pelona pass some four or five miles.

There are now two lines of daily stages to the Quijotas mines from Tucson, with fares respectively at \$7 and \$9 apiece.

Young Men's Scientific Society.

A movement is on foot to organize an association for the purpose of mutual intellectual improvement among young men. Its principal aim and object is the securing of a better and more general knowledge of all branches of science. Lectures are to be given before the society (illustrated by apparatus, etc.) by acknowledged professors in the various branches of science. Members are also to lecture before the society. Exercises are to be prepared and participated in by the members that will lead to the principal objects as given. The society to be of the nature of a deliberative assembly, and to conduct all of its proceedings according to strict parliamentary rule, and to be governed by a constitution and by-laws. It is proposed to have the society possess features that constitute the essentials of an "academy of science," "geographical society," "microscopical soci-

Long Hole Drilling.

The long hole process of sinking by the diamond drill was successfully used at the Pottsville (Norwegian) deep shafts. The main hoisting shaft is nearly 1,600 feet deep. The size of rock cut was 13 feet 10 inches by 16 feet. The other shaft is 25 feet 8 inches by 13 feet 10 inches. Four drills were used, each boring an inch and three-quarter hole, and from 200 to 300 feet deep. In the hoisting shaft 25 holes were bored about 3 feet 3 inches apart in one direction, and 4 feet apart in the other.

When completed the holes were filled up with sand and the drills were removed. The miners then commenced blasting by removing three or four feet of sand from the holes and firing them in groups. The process was continued until the bottoms of the holes were reached, when the drills were again charged and the work of drilling recommenced. A central group

Indian Signals.

We recently made an extract from the publications of the Bureau of Ethnology of the Smithsonian Institution, and gave an engraving of a form of Indian signaling. That represented an Indian signaling "Who are you? I do not know you," and the answer giving the tribal signal of "Pam."

These signals are actions or manifestations intended to be seen at a distance, and not allowing the minuteness or detail possible in close converse. Signals may be executed—first, exclusively by bodily action; second, by action of the person in connection with objects, such as a blanket, a lance, or the direction imparted to a horse; third, by various devices, such as smoke, fire or dust when the person of the signalist is not visible. When not simply intended to attract attention, they are generally conventional, and while their study has not the same kind of importance as gesture signs, it possesses some peculiar interest.

The discovery of enemies, or game, or anything else, is announced by riding rapidly to and fro in a circle. The idea that there is a difference in the significance of these two directions of riding appears among many of the Dakota Indians of the Missouri valley to be erroneous. Parties away from their regular encampment are generally in search of some special object, as game, or of another party, either friendly or hostile, and when that object is found the announcement is made in either of the above ways to their companions. The reason that a horseman may ride from side to side is that the party with whom he desires to communicate may be at a particular locality, and his movement—at right angles to the party—may be perfectly clear.

Should the party be in small bands he naturally rides in a circle so all can see him.

The latter was noticed by Dr. Hoffman in 1883 at the Yellowstone river. The Indians had concentrated after their first repulse by Gen. Custer and taken possession of the rocks and bluffs across the river. As the column rode up one Indian was seen on a high bluff riding rapidly in a circle and occasionally firing his revolver. The signal announced the discovery of the coming force. Riding in a circle he produced a lateral movement visible from any point.

THE OUTLOOK SOUTHWARD.—William L. Calhoun, Mining Recorder of Jordan District, an experienced miner and prospector, and familiar with the country south to and some distance beyond the southern terminus of the Carson and Colorado Railroad, recently returned from a three weeks' tour of observation in that section, and says that neither the business nor mining outlook along the railroad begin to compare with those of Jordan, Homer, Tioga and Prescott districts, and of western Mono generally.

INDIAN SIGNAL OF DISCOVERY OR ALARM.

ety," "society of natural history," etc., etc. It is stated that assistance is promised from such prominent men as Judge Heydenfeldt; Andrew J. Moulder, Superintendent of Public Instruction; Prof. LeConte, of the University of California; Dr. Geo. Hewston; Carl Seiler, Superintendent of California Electrical Works; Prof. Volney Rattan, Professor of Physics, Botany and Chemistry, Girls' High School. A circular has been issued by Mr. Ben Armer, of 306 Sacramento street, asking the co-operation of young men.

The Eureka Consolidated and Richmond Companies have just lowered the rate for reducing ores at their furnace to \$12 per ton. They also advertise to pay 67 per cent of the assay value of the silver and 80 per cent of the assay value of the gold in the ore. They also offer 20 cents per unit for all lead contained over 20 per cent.

A SUBSTANTIAL pledge of peace has been offered by the Apaches at the San Carlos Agency in the persons of fifty-five of their children, who left Wilcox for the Carlisle training school,

of holes was always fired first and the outside rows afterward. The outside rows of holes squared the shaft up nicely, so that little trimming was required, although many of the holes were not perpendicular and some were not straight.

An attempt was made in 1875 to sink the Hams deep pits in South Wales by the diamond drill, but after working the shaft from 175 yards to 244 yards this process was abandoned. In working large shafts the long hole process is expeditious, but the financial results do not seem to be satisfactory. For shafts, however, of moderate depth the long hole process might give satisfactory financial results; but, as stated, experience so far shows the system to be expensive.

MAJOR POWELL, of the Geological Survey, in his report for December, says that during the month Gilbert Thompson and Mark Keer, aided by their assistants, have continued the platting of material collected in California during the field season. Two square miles have been added to the surveyed area of the New Idria Mining Company.

CORRESPONDENCE.

Montana Mines.

EDITORS PRESS:—Thinking the numerous Montana readers of the Press would be interested in learning what was being done in this locality in mining and reducing ores, I have made a brief examination the past week, and the facts gathered are herewith given.

At Comet everything bears the impress of prosperity. Business men all appeared to be cheerful, and were doing a fair amount of business. There is no building going on save an addition to the hotel of Capt. Parkinson, which was necessary for the comfort of regulars and transient guests. The Comet mine is looking better than ever. The output is eighty tons every twenty-four hours. The mine is well opened with shafts and levels. The estimate of ore on dump is 2,000 tons, and there are not less than 1,000 tons in sight in the mine. The concentrator, which has just been remodeled and enlarged, handles 80 tons per day. The concentrates are hauled to Wickes, a distance of four miles, where it is put upon the cars of the Jefferson County Railroad in bulk, from whence it is shipped direct to Newark, N. J., for reduction. An average of nine carloads per week are now shipped.

The Rumley.

Adjoining the Comet, is a fine mine, and carries both free milling and smelting ores. The output is about 30 tons per day. The ore is hauled to Wickes, where the free milling is put through the mill at the rate of 20 tons daily. The base ores are roasted in Buckner furnaces and will be smelted as soon as the new furnace is completed, an event looked for by the 11th inst.

The Chester lead, in the vicinity of the Rumley, is owned by Mr. J. T. Parkinson. It is developed by shaft 51 feet in depth, and a cross-cut at the bottom shows 15 feet of rich carbonate ores, which contain from 60 to 80 ounces of silver per ton. It has only been represented, because there has been no opportunity of selling the ores or having them reduced. This state of affairs no longer exists. The owner will ere long begin working systematically.

The Pilot, the property of J. T. Parkinson and John T. Murphy, is an old location. It is developed by shaft to a depth of 971 feet, and levels run a distance of 40 and 8 feet respectively. The average width is 11 feet. Average assay, 60 ounces per ton. The ore is oxidized iron and galena.

Other Mines.

The North Pacific is an extension of the Rumley, and is owned by the same parties as the Pilot. It has been opened in half a dozen places to a depth varying from 4 to 8 feet. In one place the lode is 30 feet wide. Character of ore, galena. A tunnel has been run a distance of 280 feet, and is now within ten feet of the ledge.

The Baltimore is near the last named. It is a very promising prospect—owned by Sam Mackey; depth of shaft, 60 feet; width of lode, 7 feet. A tunnel 350 feet in length reaches within 30 feet of the ledge.

The Silver Crown lies about one mile from Comet. It is developed by shaft to a depth of 50 feet. A level has been run a distance of 40 feet, showing an average width of ore of 30 inches. The ore is mostly free milling. There are spots of galena and black sulphurets. Numerous assays show an average of 80 ounces of silver per ton. Mr. John F. Pating, the owner, has had sampled in tons select ore showing 200 ounces per ton, and has 50 tons second class on dump, averaging 40 ounces per ton.

The Wilber shows a similar class of ore as the above—is about the same width and a supposed extension of the Silver Crown. It has been opened by a shaft 65 feet in depth. There are many other lodes near Comet that are being developed, and most of them are very promising. New reduction machinery is being put up in the heart of this belt of mines, which has already given new life to development and prosperity.

At Wickes there is a new departure. The 15 stamp mill is running already as before mentioned. The concentrator has been torn out of the old works and part of the machinery taken to Comet and placed in the concentrator at that point. On account of the unfavorable location of the works, it is not probable that any more machinery will be put in.

Harbon is a New Camp.

Situated about one mile west of Jefferson City. A concentrator is being erected of a capacity to reduce 125 tons daily. This has been erected for the express purpose of reducing ores from the Alta. The machinery is of the most approved pattern from the Fort Scott, Kansas, foundry.

The Alta is the best developed mine in Jefferson county, if not in all Montana. The daily output is about 60 tons. The ore is now hauled from the mine to the concentrator—one mile—but it is in contemplation to construct a tramway so soon as the weather permits. Mr. Lyman Rumley, an experienced and able miner, is foreman of the Alta, and he is certainly the right man in the right place.

The concentrators are Comet and Corbin; the reduction works are Wickes and the Rumley. Comet and Alta mines are the property of the Helena Mining and Reduction Company, D. C.

Corbin, Esq., is General Manager, Mr. Langmaid, Superintendent, and Mr. Gilbert Assistant-Superintendent. It is estimated that more than half a million of dollars have been squandered on these mines and reduction works the past eight years, owing to inefficiency of the management. The new company is composed of energetic business men who have abundance of capital at command and a disposition to run the works and mines for all there is in them. JAY C. KAY.

Jefferson City, Montana, Jan. 15, 1884.

Elko Mines, Nevada.

[From our Traveling Correspondent.]

EDITORS PRESS:—The Elko county mines, located in early days, were many of them simply located and one year's title made to them, and then neglected to follow some new attraction. Men of more means were making more permanent developments.

About 18 miles from Elko, to the west, and a little south of the Tuscarora stage road, is the Lone Mountain or Merrimac Mining District, located in '69, though little work was done till '79, and even yet the district is not at all prospected. This season, however, there are parties contemplating more thorough work than has yet been done. This district is rich in copper, as indicated by the specimens I saw, and the copper as I saw it taken from the scowier assay as made in the assay room of the School of Mines.

The samples I got from Mr. W. J. Morris, who is interested in some of these claims, were good copper ores. He has so far prospected by shaft on a contact vein lying between granite foot wall and limestone hanging wall. The outcrop of this vein is traceable for more than a mile over the foothills of this district. At a depth of 60 feet no water, but a full 3 feet of pay ore, and width of 5 feet between walls. The assay value in copper and silver is nearly \$200 per ton.

The access to the mine is easy from the Elko road, and it is only three miles to a large stream of water sufficient to run a smelting furnace. There is also another stream of water in the district of about 200 inches.

Sage wood is near and plentiful, but larger wood is to be had about 14 miles distant. I was told that all the needed fluxes are plentiful within the district. By two miles grading an excellent road of only eighteen miles length is secured to Elko. The ores are principally copper glance, red oxides and gray copper, and are considered easy smelting ores.

I was not able to visit Railroad district to the south of Elko, but she is able to speak for herself, as her crude copper-silver bars can be seen piled up at the depot awaiting shipment. It, too, is gradually moving on and contributing a small share to the world's stock of useful metals. Many old locations in various quiet districts will now be looked after. The outlook is more encouraging than for some years back. The improvements in processes of working and reduction on ore transportation has given some new encouragement. From Reno to Deuver, where formerly \$45 was charged, the freight is now reduced to \$15 per ton.

B. W. CROWELL.

LITIGATION NOT ENDED.—Although the decision of Judge Sawyer was against the miners on all points in the late case, it does not follow that this will end the litigation. The mining interest is too great; the capital invested is too large a sum; the welfare of too many communities involved; and an existing belief that there are equities on the mining side of the question that will not admit of giving up the contest until the United States Supreme Court, the last tribunal of judicial resort, has passed upon the case. To this and the mining communities of the State, which are all, to a greater or less degree, interested in the question, should give assistance. Heretofore the litigation enforced against the miners has been cared for by the State Miners' Association; had it not been for this organization no one company would have been able to have carried on the contest which has been made. The expense has been enormous; but yet the magnitude of the property interests involved justified it. To take an appeal to the United States Supreme Court, other large expenses will necessarily be incurred; to meet it the hands of the State Association must be strengthened. There should be the organizing of local associations in every mining county, by means of which funds can be collected, and more complete unity and understanding among the people be brought about. Heretofore the people, believing in the justness of their cause, have not taken the general interest in sustaining the association that they should have done, believing that the decisions of the courts would be favorable. Now that the Sawyer decision strikes a blow that will result in the most disastrous consequences if not averted, the people of the mountains must all stand together and fight this question to the end, the Supreme Court of the United States, where, if the miners have any legal rights they will receive full recognition.—G. V. Union.

BORAX MARKET.—Something is up in the borax market, it is hard to tell just what yet. Prices in Liverpool have dropped 20 per cent. New York is pretty firm, however. It looks as though there would be a struggle. Smith Brothers and W. T. Coleman, the largest manipulators on this coast, are out, and the chances are for war.

Gold Quartz for Jewelry.

The Call has an article on the subject as follows: Among the growing industries of our State, the manufacture of quartz jewelry deserves notice from the fact that it is a San Francisco specialty, for as much of it is made and sold in this city as in all the rest of the world, probably. In the pioneer days, small nuggets of peculiar shape were favorite ornaments with either sex, their mountings being confined as a rule to pins, rings, brooches, ear-rings and watch charms, but these nuggets have almost entirely disappeared since the miner's cradle song is no longer heard in the land, and their place has been usurped by the free gold-bearing quartz which is produced in many of our mines. So great has become the demand for this quartz jewelry of late years, that those who manufacture it often find the supply of proper material inadequate to their needs, and attempts have been made to replace the genuine with an imitation article. Up to the present time, however, these attempts have been unsuccessful, for the counterfeit gold quartz bears upon its face such tell-tale marks of forgery that no one who has ever seen the real one can be deceived for a moment. Some years ago a man by the name of Thiery thought he had discovered the secret, after a long series of expensive experiments, but experience proved that he had lost both time and money. His plan was to subject non-mineral bearing quartz to an intense heat until it was reduced to a fluid condition, and then to throw into the molten mass small lumps of heavily alloyed gold, and then to mould, or, after it had cooled, to run the fused composition into the required shapes. The result was satisfactory so far as the mingling of metal and stone was concerned, but a complete failure as a fac-simile of the thing it was intended to represent, for the quartz was reduced to a milky, glass-like appearance, that was anything but natural.

The Latest Effort

Made in this direction has just come to grief, and is another added to the numerous instances of duplicate invention to be found in the Patent Office at Washington. Messrs. Ledue, Connor and Laine devised a method for imitating gold or other mineral quartz by the use of electricity, and applied for a patent, but found, to their astonishment, that an almost identical patent had been issued to a New York man nearly fifty years ago. This, of course, prevented their obtaining the desired letters, although no evidence could be found that the original patent had been intended for jewelers' use, or for that matter, had ever been utilized at all. Notwithstanding the fact that they could not secure a monopoly, the parties in question thought they could make money out of their theory by putting it in practice, and advertised themselves as manufacturers of jewelers' quartz. Like every other effort, however, this one has proved so unsatisfactory that it has been abandoned. In the first place, the imitation was palpable, and in the second, the false ore cost very near, if not quite, as much as the genuine. It is asserted, with what truth only the parties themselves can say, that several jewelers in this city have wasted considerable sums of money in the manufacture of bogus ore, and this fact simply proves how large an amount of the simon pure is used, as each individual piece of quartz set as a jewel can have, at best, but a small intrinsic value. Such jewelry is worn as a curiosity, and a comparatively small amount of it only is sold to resident Californians—for personal wear, that is—the great bulk of it being purchased by visitors from the East, or as presents for Eastern friends. In one establishment where a great deal of this jewelry is manufactured, the manager states that most of his sales are made during the late spring and summer months, and that the demand has been so great at such times within the past two years that almost his entire force of workmen has been employed in supplying it, and that his sales would have been much greater had the necessary material been obtainable. Further evidence of this last statement will be found in

Prices Paid for Such Quartz

As is available for jewelry. The free-bearing ore used for this purpose must have its gold so perceptibly massed that it will present a handsome appearance when set in a trinket, and it is only by sorting over tons of valuable ore that a small quantity of these special pieces can be found. The gold found in California quartz averages in value about \$16.50 an ounce, but the jewelers buy such ore as they can employ at the rate of from \$20 to \$30 for each ounce of gold it contains, the price varying in accordance with the beauty of the specimen. Without devoting a great deal of time to hunting up the statistics on this point, it would be impossible to give even an estimate of the aggregate amount paid by our jewelers annually for their quartz, but a hint may be found in the fact that during the past year one lapidary, who employs a very few assistants, purchased nearly \$10,000 worth of ore, while during that period the manufacturing firm above mentioned expended nearly \$15,000 on the same material. The supply, to a certain extent, keeps pace with the demand, for the large prices offered for handsome specimens make a more careful search for such specimens profitable to the miners and mill-owners. To a considerable extent the jewelers are supplied directly from the mines, but a majority of their ore is

obtained through a prominent assay office in this city, where the collecting of this kind of quartz is made a specialty. Great care has to be taken in its selection, for the stone used must be solid enough to bear the rough treatment of saw, chisel and polisher, all of the ore being brittle, while much of it is so friable that it would crumble to pieces under the jar of the instruments. For this same reason, all the pieces set in jewelry or cabinet work are small, the largest that the writer has seen being only four inches long and two inches wide, and those were referred to as of extraordinary size. The saw hangs so in the gold that it is apt to split the wafer-like slabs, as they are being cut from the parent rock. Not more than one-half of the ore purchased finds its place in golden settings, as the other half has been wasted in the preparing—wasted for ornamental use; that is, for the dust and chippings are of course smelted and robbed of their precious metal.

Determining the Gold.

The method for determining the amount of gold contained in each piece of quartz has been greatly simplified by a well-known assayer in San Francisco, who after long years of practical experience and careful study, has arranged a standard table, which shows to a fraction the proportionate weights of gold in a mass of auriferous quartz, when the specific gravity has been determined. To obtain the latter, the ore is first weighed in air and then in water, and the difference being divided into the large sum gives the specific gravity. To explain this more clearly, let us study the process upon a certain lot of ore: In the air it weighed 1,504.5 ounces, in water 956.35. Subtracting the latter sum from the former, we find the difference to be 548.12, and, dividing the last into 1,504.50, we discover the specific gravity to be 2.75, or, in other words, that the auriferous quartz in question is two and three-quarter times heavier than water. Having arrived at this result, we turn to Mr. Price's table, and after a simple calculation, determine the fact that the 1,504.50 ounces of quartz contain exactly 95.08 ounces of gold. This gold in the market was worth about \$1,570, while a jeweler paid for the ore \$2,375; that means that he paid \$805 more than the miner would have obtained at the mill, this large surplussage arising from the fact that the ore was especially well suited to the jeweler's use.

The Designs Used.

When mineral bearing quartz was first utilized for ornamental purposes, and that dates back to only a few years ago, it was fashioned into simple shapes and was modestly mounted, but as the taste for it increased, so did its intricacy of design and elegance of setting, until at the present day it is employed in every conceivable form of jewelry, and in other articles of personal or house adornment too numerous to mention. Coming in the distinct colors of white, black, red and blue, with many of the shades between, and sparkling with its gold or silver, it offers rich material for artistic combinations of color in the ornamenting of gold and silverware of all descriptions. It is also paneled in certain kinds of furniture, its effect being in such cases greatly enhanced by the added colors of iron and copper pyrites, of cinnabar and other rich-hued mineral or barren rocks. Into many other forms than these is the gold-bearing quartz fashioned; such as into cane-heads, perfume bottles, parasol handles, fan sticks, etc. An estimate of the selling value which jewelers put upon it may be based upon the fact, that according to size, but without regard to the metal in the stone, they charge for the gold quartz setting in a ring from \$2 to \$2.50, and these settings are scarcely a tenth of an inch in thickness.

In conclusion, it may be truthfully said that this young industry has already added many thousands to the product value of our mines, and that it gives lucrative employment to a large body of skilled mechanics.

REPORTS FROM A PROSPECTOR.—Day before yesterday we met Mr. W. F. Terris, of Providence, in town. He informed us that he had been out prospecting for several months among ranges of mountains that had hitherto been unprospected. He prospected the Kane Spring range northwest of Danby to within a short distance of the Colorado river. He found no mineral deposits, and no signs of water with one exception, until after the rain storms, when small quantities of water were found in "tanks." Limestone and iron are the principal characteristics of the mountains in that region. He discovered a large mountain of iron rock, and if it is of value for commercial purposes it will afford an inexhaustible supply of iron ore. From Mr. Terris we learned that Mr. J. P. Van Winckle and Joseph Boland have discovered a fine looking prospect eighteen miles southeast of Danby station. The ledge is located in a limestone range. The vein has been stripped for a distance of 100 feet, showing an average width of three feet, the foot wall consisting of porphyritic granite, and the hanging wall of slate, running east and west. Very little ore has been taken out. Assays taken so far range from \$50 to \$800 per ton. The indications are that there is a large body of ore there that is, principally low grade. A spring of brackish water is situated within three miles of the mine. The mine is called the Grand Central. A good, natural wagon road leads to it from Danby. The owners are confident they have a good piece of property and are preparing to sink a shaft on it.—Calico Print.

MECHANICAL PROGRESS.

Method in the Workshop.

Method, or system, is a workshop virtue which all touch upon. This is not given to all men to possess. Some men have no system; they are always in a muddle. At times they get hopelessly blocked, and others have to put them straight. Method implies foresight and a logical mind. A man must think of his work, and arrange it beforehand to the best advantage. A workman manager without method is useless. He will have his smithwork done before his patterns are begun; one set of men will be waiting for another set; his work will always be behindhand, and the cost of production greater than that at works where there is a good system.

Business is, perhaps, not so apparent a virtue as the others we have mentioned; but every foreman or manager knows how pleasant it is to deal with a workman ready at taking a new idea, or willing to try a new method of doing work. These are the men who distinguish themselves, and obtain better positions than those who cannot move out of their rut of habit. So also a firm becomes noted for adapting itself and its resources to new trades or methods of doing work, while a firm which will not try an experiment will be pushed out in the cold in the struggle for existence. Knowledge of the principles involved in workshop practice is the last of the workshop virtues we shall refer to. The man who knows the reason for what he does is a better man than he who does a thing because he is told to do it a certain way. Every mechanic should understand, for example, why his drill should run faster for a small hole than for a large one; why one speed of tool is suitable for one metal and not for another.

If he is a smith he should know why steel is worked at a lower heat than iron; what conduces to a sound weld, and why a piece of steel broken haphazard off a bar cannot be drawn to a sharp point without certain precautions. There are principles underlying every trade which it is to the interest of every artisan to study, to ponder over, and even to discover, for it is well known that there are principles yet undiscovered which the cultivator of the various workshop virtues may be lucky enough to fathom, with honor to himself and benefit to mankind at large. —*London Mechanical World.*

Interesting to Workers in Metals.

Professor Egleston, of Columbia College, New York, has written the following letter to the editor of the *Mechanical News*: "For some years past I have been making investigations on metals and alloys of all kinds, and have arrived at a point where I am very anxious to secure specimens to investigate the effect of compression. Will you be good enough to announce the fact through your journal and ask the manufacturers of metals and alloys of any kind to send me specimens for that purpose. The specimens which I wish for the investigation of compression are, first: Three pieces, two inches in diameter and three inches long for each examination; second, two pieces, each one inch in diameter and four inches long; and third, about three pounds of clean filings of the same kind of metal or alloy as the specimens sent. I should like to make at least three examinations of each metal, which will make fifteen pieces in all—nine of the larger, six of the smaller and nine pounds of filings.

As these investigations of compression are made at very great cost, and as I am making them for scientific purposes only, without remuneration of any kind, in the hope of discovering some facts which will be useful to manufacturers, I shall be very glad to make besides comparative tests other than compression; and also analyses of the metals and alloys for their actual cost to me, making no charge for my time or services. The results I have already obtained are such as lead me to believe that the results of the investigations I am about to make will be of great interest to all persons using metals of any kind for construction. A few very liberal gentlemen and firms have supplied me with the amount necessary for the investigations on compression, but I have no funds to make the comparative tests on tension, torsional or transverse strain, and I therefore am willing to do them for their actual cost to me, and request your kind interest in making my purpose known to your readers, and asking their assistance.

LATHE PULLEY FACES.—Machinists have often noticed the edge wear of belts on pulley steps of lathe cones, caused by the riding or the rubbing of the belt on one step against the rise of the next higher step; and this creeping up notwithstanding the swell or crowning of the face of the pulley step. A recently noticed remedy is one that is applied by the Pratt & Whitney Company, Hartford, Conn., on all their lately built lathes—a remedy as simple as it is effectual. The crown of the pulley face is not in the center, but on the "off" side, or toward the next lower step, away from the adjoining rise. By practice it has been found that this diversion from the center is too slight to affect the eye, tho' off on a step of 2½ inches for a 2½ inch belt being only ¼ of an inch; but it is an effectual remedy. The crowning of the

faces is effected by equally simple means. Machinists generally know the Slate taper attachment to lathes, which guides the tool carriage independent of the traverse screw, in turning or in boring tapers. The arrangement for producing the swell is on the same principle, the traverse screw being removed and the upper portion of the carriage with the tool post being held by a flat spring at the back of the lathe against a former, a slightly swelled strip to correspond with the intended crowning of the face of the pulley step. This is the last turning operation on the lathe cone, the former clips being in line or level.

PAINTING IRON.—The following experiments on preservatives for iron have been made under the auspices of the Dutch State railroads: Sixteen iron plates were pickled in hydrochloric acid, then neutralized with slaked lime, rinsed in hot water, and while warm rubbed with oil. The same number of plates were cleared of scale, so far as it could be removed by brushing and scraping. Four plates from each set were then painted alike—namely, four plates with coal tar and four plates with iron oxide A, another set with iron oxide B, and the remaining set with red lead. They were then exposed three years, and the results observed were as follows: The coal tar on the scrubbed plates was quite gone; that put on the pickled plates was inferior to the others. The iron oxide A on the scrubbed plates was inferior to the other two, while on the pickled plates it held well; the oxide B was found superior to that of A, but inferior to red lead, while the plates covered with red lead stood equally well on both prepared plates, and were superior to all others. From these results it is evident that pickling the iron removes all the black oxide, while scrubbing does not. It is also shown that the red lead unites with oil to form a hard oxy-linseed oil acid soap—a harder soap than that given by any other combination. The red lead is shown by these experiments not to give way under the scaling; it is more adherent to the surface, more elastic and cohesive.

A MECHANICAL TEST OF COKE.—The *Cleveland Trade Review* has the following interesting statement: "The fact that a great deal of bad coke finds its way into the market has called for some kind of a mechanical test, whereby its real value for iron-smelting can be arrived at, practically and accurately. Of course chemical tests can be made, but these are not always attainable or satisfactory in practice. To meet this want, a Cleveland furnace manager has been experimenting with a mechanical testing machine of his own device, upon half-inch cubes filed out of different varieties of coke, with very interesting results. We cannot yet present those results in figures, but enough has been accomplished to demonstrate that the furnace value of the coke is in direct proportion to its ability to resist pressure. In other words, the longer it has been burned, up to a certain limit, the better it will resist mechanical pressure, and the greater its value for smelting purposes. The device used is in form an ordinary testing machine, with lever combination. Cubes of the size stated (half an inch face) were found to be of the best size for testing. The results of these experiments will be awaited with interest by iron workers generally."

A NEW ROTARY ENGINE.—An announcement is made from Stevens' Institute of Technology, of considerable importance to mechanical engineering science. A Noteman rotary engine was placed there recently for experimental purposes, and accomplished results which Professor Thurston states in his report, will probably surprise other engineers as much as they surprised himself. The tests consisted in the determination of the gross and net power of the engine by an indicator and dynamometer, the consumption of water and steam, the friction of parts and of the engine as a whole, and the action of the inertia in the production of unbalanced stresses. For more than fifty years inventors have vainly endeavored to construct a rotary engine sufficiently light to run with economy as to steam and friction. It was found that the Noteman engine's "consumption of steam, and consequently of fuel, was vastly less" than that of reciprocating engines, and "it possesses minor advantages, such as fast running, reduced weight, and compactness as well as simplicity of general plan, and small cost of construction."

EFFECTS OF HEAT ON SAW TEETH.—A correspondent of the *San Mill Gazette* says: "Heating of saw teeth to a blue with an emery wheel injures the teeth. In the first place it destroys the temper; in the second place the emery wheel causes a surface glaze to form, which a file will not take hold of, and after swaging you are compelled to finish with a wheel; then you have a tooth without temper, on which you cannot get the keen cutting edge that you could obtain with a sawge and file." Another correspondent of the same journal says: "I have gummed a great many cross-cut and mill-saws with emery wheels, but when I consider the job finished I am very careful to leave all parts of the tooth bright where the wheel has touched it. Although the teeth are quite blue during the operation, I have never discovered that any injury is done, provided the blue is all ground off and the tooth left bright as if it had been filed. I see no reason why an inserted tooth should be injured more than a solid one."

SCIENTIFIC PROGRESS.

The Uniformity of Nature's Laws.

An interesting lecture was delivered recently before the Vienna Academy of Sciences, by Dr. W. Meyer, on the above subject, in which the lecturer explained that the latest astronomical discoveries showed very plainly the system upon which the universe is founded. Respecting the qualities of light, the Professor explained that it passes from all the stars to the earth with the same degree of velocity that the earth's light travels to the stars. The results of spectral analysis were resumed as follows: The analysis of the sun's light to the original shades of colors has shown us twenty-five chemical elements, which all exist on our earth also, and no wholly unknown matter has as yet been ascertained. The sun is composed of the same materials as the earth. The sun may be considered the mother of the earth. But the distant fixed stars are of a composition similar to and in many cases identical with that of the sun. The red stars are heavier than the white. Then the stars which appear as new to us, not having been observed in the heavens before, develop a glowing atmosphere of hydrogen around themselves. The nebulae in the firmament are caused probably by hydrogen and nitrogen, but it is possible that they are composed of a form of gas unknown to us. The warmth of the stars has also been ascertained. Red stars are the warmest, green stars the coldest, whilst the white stars have a medium temperature. The laws of gravitation are common to the whole system. This is proved by the so-called double stars, which revolve around each other by the same laws which regulate the movement of the earth around the sun. The law of gravitation is so plainly visible that the satellite of Sirius was not discovered until it had been ascertained that there was an attraction which worked its influence upon the star. The uniformity of nature's laws and the similarity of the materials composing the universe are a sufficient proof that there must be organizations similar to that of our system all over the universe. We see the results of these laws in the world we inhabit, and there can be no doubt that the same powers and the same materials have produced organizations similar to that of the earth in millions of other places, although we can but philosophically suppose their existence, not practically prove it. We must imagine that the earth is inhabited by a small family forming part of the great nation which peoples the universe.

THE GOSPELS OF WORK AND REST.—Dr. George M. Beard and Mr. Herbert Spencer almost simultaneously sound the alarm against our modern worry in the words "The gospel of work must make way for the gospel of rest." An English writer, signing himself E. S., protests, in the *Journal of Science*, against a theory of civilization which makes the acquisition of material wealth almost its sole object, and which brands all men not engaged in such pursuit as idlers. "We have under its inspiration stripped our own country, over a great and increasing part of its surface, of every beautiful feature. We have blackened its skies with smoke clouds, polluted its air with sulphurous acid, filled its streams with liquid filth, covered its hills with 'spoil-banks,' blighted its green fields, cut down its woods, and extirpated many of its most lovely animal and vegetable species. Our cities, from London downward, present, as their main feature, meanness, monotony and ugliness by the square mile, rarely, indeed, relieved by a street or building upon which the eye may rest without pain." The diseases caused by over-work, public morals, and the effect of our system on true intellectual progress, receive vigorous treatment. The author concludes that our industrial civilization is found wanting in every particular. "It has broken down more rapidly and more disastrously even than the military regime which preceded it, and will be found to have left upon the human race even deeper marks of its failure."

AN IMPROVED PHONOGRAPH.—One of the most interesting exhibits at the late Vienna Electrical Exhibition, was Gentilli's glossograph, a little instrument by which speech is automatically reproduced as soon as it is uttered. A small apparatus is placed in the mouth of the speaker—in contact with the roof of his mouth, his tongue and his lips—and on being connected with an electro-magnetic registering apparatus, the sounds are committed to paper. It is constructed in such a manner as not to cause any inconvenience to the speaker; neither is it necessary that the voice should be raised, as it reproduces a whisper as exactly as a shout; the only condition is a correct articulation. According to the inventor's calculation, it will be possible to write four or five times as fast by means of the glossograph as has hitherto been possible even by the quickest writer. At first sight it appears as if this invention was but an improvement upon Edison's phonograph; it is, however, of a much older date. It rests, unlike the former, on an acoustic principle, and does not reproduce the sounds in a microscopical form. The chief obstacle to the introduction of the glossograph will be the difficulty in deciphering the characters; but it is not impossible that, with the help of a second automatic apparatus, the characters produced

by the glossograph may be translated into our common type-writing. The orthography would doubtless appear strange, but in these days of phonetic spelling this might not long be a hindrance. —*Pall Mall Gazette.*

TELEPHONING OVER THE SEA.—Experiments were recently made on the large wire of the Postal Telegraph Company between New York and Meadville, Pa., a distance of 509 miles, with a telephone devised by Prof. Webster of Ypsilanti, Mich. Owing to the storm and atmospheric conditions the magneto bell was kept jingling by the induction alone, but there was little difficulty in carrying on a conversation.

What Prof. Gillett calls a ten-point instrument was used. Each point, Prof. Gillett says, is like adding another telephone in power. The feature of the receiver attached to the telephone is the increased magnetic surface presented to the diaphragm. Chicago, a distance of 1,010 miles, including a cable containing twenty-two wires, has been reached satisfactorily with a ten-point instrument.

One of the principal objects of these experiments was studying the possibility of constructing an instrument by which telephonic communication can be had across the Atlantic ocean as well as over long land distances. To effect this result, a twenty point instrument is being made for the purpose of ascertaining the distance it will reach. Prof. Gillett said that the French cable was 2,436 miles long from end to end, and the resistance was 2.89 ohms. The resistance of the wire used in the above experiment was 1½ ohms, but as satisfactory results had been obtained from the smaller copper wire, the resistance of which was six ohms. "We feel confident that before we get through we are going to say 'Hello!' and a good deal more, too, to the people on the other side," said Prof. Gillett. "What we are aiming at is communication at long distance."

THE NATURE OF ELECTRICITY.—Professor Thompson has shown how a series of floating magnet poles of like name, repelling one another, tend to produce equal distribution of the poles. Prof. Thompson, arguing from the second law of electrostatics (inverse squares), sought to explain the first law in a rational manner, on the hypothesis of self-repelling molecules, which tend to uniform distribution. When there is a surplus in one part and a deficit in another, the molecules are urged toward each other, i. e., attract. This was shown by putting a surplus of floating magnets at one part of the basin. By the movements of these magnets, when confined in barriers and with surplus and deficit purposely made, the author imitated the effects of a Leyden jar, induction, a battery current, etc., the motions and arrangement of the poles illustrating the hypothetical behavior of electricity. The author was led by the hypothesis to infer that either the ether is electricity, or that the ether is electrified, and the former seemed the simpler conclusion.

LOWER CALIFORNIA.—The southern part of the peninsula of California has recently been explored by Dr. H. Ten Kate, who reports that there are no longer Indians of pure race dwelling in that region. The blood of the ancient Periculis and Coras flows, it is true, in a great number of Metis, but they resemble the Spaniard far more than they do the Indian. A few relics are found in the graves, and here and there on the cliffs rock paintings are found. The paper concludes with an account of the finding in Sonora, Mexico, under large masses of lava, objects resembling fishes and turtles, some cut out of marble and others cut out of a hard green rock. Stone knives smoothly polished were found in the same locality, on the seashore and about twenty-five feet above high water mark.

FOUND IN THE GREAT DEEP.—The United States Fish Commission steamer, the *Albatross*, has worked in greater depths than have ever yet before been sounded with such heavy trawl, having dredged 2,949 fathoms, or about three and one-third miles, and brought up living creatures from this depth. It required 41,000 fathoms of steel rope to accomplish this feat and over three hours to pay it out. This in latitude 37.12 and longitude 69.39, about 300 miles from No Man's Land, or half the way to the Bermudas. At the bottom were found globigerina, or the soft ooze common at great depths, and several species of fish hitherto unknown to science. A peculiar scarlet shrimp about a foot in length, with an enormous quantity of eggs, each containing a large globule of oil, were found.

A DRY GALVANIC BATTERY.—Electro-piles without fluids were among the earliest forms invented, but they had but very little power, and although they last a long time, have very little value. They are now beginning to attract attention again, and C. Schneler, of Dresden, has invented one consisting of a copper cylinder open at both ends, in which is placed another open cylinder of amalgamated zinc. For filling, he mixes up plaster of Paris with a saturated aqueous solution of chloride of zinc, containing 7 per cent of common salt. A stiff paste is made in this way, and poured in the annular space between the two cylinders, where it soon hardens and sets. The electromotive force is not stated.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MINING ABOUT BUTTE CITY.—Amador Ledger, Jan. 26: The four-stamp mill of W. E. Stewart was moved last week from the gulch to a point below the Confidence mill. The Confidence mill has just got through with a crushing of rock from its own mine. The Mello Bros. have made arrangements to have a ton of ore from the ledge recently uncovered by them crushed at the Confidence mill. This is intended to test its paying qualities by mill process. That the rock carries gold in paying quantities there is no doubt. It is so exceedingly fine, however, that the question to be decided is whether it can be saved by the ordinary methods. J. Stewart has hauled a quantity of rock to the Confidence mill to have it crushed. Herman Tripp was to have started his one-stamp mill above Big Bar Bridge last week, but difficulty with water prevented it. J. Morgan and W. F. Detert, examined the Mello claim Thursday of last week, and were favorably impressed with it.

Calaveras.

MURPHY'S.—Calaveras Citizen, Jan. 26: Considerable activity is noticeable in mining matters in our immediate vicinity, and the outlook for a boom of some magnitude is very flattering, not only among us but throughout the whole mineral belt; indeed, good reports are coming in from every portion of the State, particularly from Mono county. In the Standard and Bodie mines a large rich body of ore has been encountered at a greater depth than yet found. And in the Clifton another important strike is reported. From these strikes more importance is attached to the finding of free gold and rich float, last summer in Alpine county, by a party of prospectors from Murphy's. Alpine county lies about 50 miles east from here, and at about the same altitude. The formation is similar to that found in Bodie. It is the intention of the same party to start for this region as soon as spring opens to thoroughly prospect the district. One of the most important strikes made in this vicinity for years, was made in the last two weeks by John Saltuary, an Indian creek, near Davis' ranch. The lode is two feet wide and is rich in free gold. It is estimated by experts that it will mill \$100 per ton. The vein is traceable 800 ft. The extensions are all taken up. There is no little excitement in regard to the find, and prospectors are out in force. The mills in this vicinity are all busily engaged in crushing ore with fair success. Murphys bids fair to keep up her bullion producing efforts and outstrip all the neighboring towns in a progressive movement in the march of improvements.

NOTES.—Calaveras Chronicle, Jan. 25: Very rich rock has been struck in the Carey mine near West Point. We were shown a specimen of the rock this week that for richness exceeds anything of the kind we have ever seen. The main shaft is now down 90 feet, from which levels have been run north and south. Width of ledge, 2½ feet. The mine is supplied with steam hoisting works. The mill on the Scorpion mine, near West Point, was started up Friday morning last. The mine is paying well. Extensive furnaces are soon to be erected in that district for the purpose of roasting the ore, as by this method it is made to yield a much larger percentage.

El Dorado.

NEW MILLS.—Georgetown Gazette, Jan. 25: The new ten stamp mill on the Eureka started up last Saturday without a hitch, and the perfect manner in which it works is the admiration of all. It is acknowledged by all familiar with quartz mills, to be one of the best mills they ever saw run; indeed, our people are delighted with it, and the universal sentiment is that Benjamin, the millwright, and Morey, the foundryman, are the men to put up a good mill every time. The mill is crushing about 25 tons of quartz every 24 hours. The Supt. will soon have the expenses of the mine brought down to a minimum, when he will be able to inform the owners what ten stamps will do for them. If favorable, two or three more batteries will be added right away.

THE MINES AT GRIZZLY FLAT.—Mountain Democrat, Jan. 24: A correspondent writes us that all of the mines at that lively camp are working full handed excepting the Flag Staff and Mount Hope; that the water is being kept out of the latter, and that one of the principal owners is expected from the East right away to start the mine up again.

THE SACRAMENTO MINE.—Arrangements are being made at this mine for the use of Burleigh drills in the tunnel to be operated with compressed air.

Fresno.

DEVELOPMENTS.—Fresno Expositor: The mining interest of this county are liable to have a boom this summer. Excellent developments have been made in the mines in Pine Gold district, and in others in the vicinity of Fresno Flats, while some good leads are known to exist on this side of the San Joaquin. The Mt. Raymond mines will probably come in for the greatest attention, as there is considerable talk in reference to them in mining circles. The San Pedro Company recently shipped 80 tons of ore from one of the Mt. Raymond mines, and had it worked by smelting process, and were rewarded with a yield of \$50 per ton. The ore is of the quality known as argenteiferous galena, or silver bearing lead. In fact silver seems to be a leading metal in all the quartz mines of this county. In the annual report of the silver output prepared by Wells, Fargo & Co., Fresno county is credited with a yield of \$20,000 in silver from its mines. The estimate is rather under than over, as all the gold taken from its mines is heavily alloyed with silver. Work has been resumed on the Mammoth mine on the eastern slope of the Sierra, in Mono county, but near the Fresno county line, and good pay ore is again being taken out, and there is a strong probability that extensive work will be carried on there during the coming summer. The North Fork mines, being in a direct line between Mammoth and Mt. Raymond will feel the influence of the activity in those districts, and of course considerable prospecting will be done

there, and we would not be surprised to see some valuable silver mines developed there. The reported sale of the Quartz mountain mine to a French company has not been effected. During the past year the quartz mine of this county have received some attention from mining men, and experts who have traced the precious metal belt claim that the rich formation that gave to Bodie its prosperity extends through the Sierra into the county of Fresno.

Mariposa.

BUENA VISTA MILL.—Mariposa Herald, Jan. 26: The new ten stamp mill at the Buena Vista mine started last week. Eight men besides the three O'Gorman brothers are at work in the mine and mill. There has been no recent developments in the mine, but a new level will be opened up 80 ft from the surface in about two weeks. They calculate that there is enough ore in sight to run the mill for five years without doing another stroke of dead work.

ENTERPRISE MINE.—Mariposa Gazette: The engine and boiler, which was recently sold at the Malone mine to satisfy creditors, was purchased by Ralph W. Barcroft, of Hornitos, for \$700. The boiler was new, and the whole outfit, it is said, could not be replaced for double the amount. The Malone mine, which was, at considerable expense, opened by John Mitchell & Co., was beginning to develop excellent ore, with a vein some two feet thick. Mr. Barcroft will remove his machinery to the Enterprise mine about three miles north of Hornitos. This is an old mine and bears a good reputation.

Mono.

THE DETROIT COPPER WORKS.—Bodie Free Press, Jan. 24: From reliable sources it is learned that the Detroit Copper Works, in Jordan District will renew operations as soon as financial difficulties can be adjudicated. The management will be entirely new and fully experienced in the practice of copper reduction. There is no doubt but that the concern can be made to pay handsomely, with somebody in the directorship who knows what he is doing.

A GOOD PROPOSITION.—It is proposed, among a few men who have faith that all the gold in the Old Mono Diggings has never been brought to light, to purchase an artesian well-boring apparatus and prospect the ledges in the vicinity where so much gold was taken out in 1862-3. The country rock is decomposed granite, which can be easily bored into. It is an experiment that promises good returns. The placer ground was wonderfully rich there, and there may be a bonanza for him who finds the fountain head.

COPPER.—Homer Index, Jan. 26: The joint shaft on the Mariposa-Coyote claims of W. L. Callahan and C. A. Wetmore, on Copper creek, some distance north of the old Detroit copper mines, in Jordan district, gives strong indications that there are larger and richer copper veins in that district than those worked by the Detroit Co. As the vein at the surface showed but traces of copper and was rich in gold, it was being worked for the last named metal, and in order to develop the mine for more economical working a tunnel was started near the base of the mountain to tap the lode at great depth. This tunnel was driven in 60 ft, but as the weather continued favorable for out-door work, the owners continued to resume sinking in their shaft on the vein, and the result is the development of a 7-foot vein of rich copper ore carrying a high percentage of gold. The Hyena, situated on the west side of Lake Canyon and believed to be the continuation of the Gorilla lode and owned by Mike Noonan and others, is being actively developed by tunnel following the vein in under the perpendicular wall of the canyon. The tunnel is now in about 127 ft, but is not yet under the solid wall, and hence is still in the disturbed portion of the vein, though the whole fissure (five ft in width) is filled with vein matter—a mixture of quartz, porphyry and clay—and in the last few feet run the quartz has rapidly increased in quantity, and prospects well. H. V. Pullen, who had the perilous adventure on the Mount Lyell glacier, has two locations on an immense quartz lode cropping out parallel and close to the southern line of the glacier, and trending down the mountain with the ice. The claims are called the Colorado and the Surrender. The Gem, on the northern slope of Mount Gilcrest, and owned by N. M. Parsons, of Bodie, is showing well in the tunnel being run in on the ledge by C. F. Caven and Joe Thompson, under contract. Bagby's tunnel, following the Grizzly lode into Mount Scowden, is now in 165 ft, and the vein shows marked improvement in the last ten feet. The May Lundy mill closed down yesterday afternoon. The mine is in charge of a watchman.

Nevada.

NEW YORK HILL.—Grass Valley Union, Jan. 25: In sinking a winze from the north drift of the 1300 level of the New York Hill, some specimen rock has been obtained in the last few days, the gold being free from the sulphurets. The indications are considered encouraging, and the winze will be continued deeper in the expectation of opening up a body of good paying quartz. The ledge from the north drift of the 1100 level, is also showing quartz of good quality and containing plenty of sulphurets. It is found that the ledge in the mine which went off quite flat from the foot-wall to the hanging-wall from the 1200 level is dipping again to the foot-wall, which is also another satisfactory indication that the mine will be all right upon deeper working. There is plenty of gold in the New York Hill yet to be brought to the light of day.

SLATE RANGE.—Work on the Slate Range mine, at Forest Springs, is going on steadily under the Superintendence of G. S. Brown. The shaft is down nearly 250 ft, showing a vein of varying width, from a few inches to two ft. A new level is being opened at the depth of 200 ft. The quartz extracted is crushed at Sothern's mill. The mine is paying expenses, which is doing well for a new venture.

THE PENNSYLVANIA CON. M. CO., the location of ground being east of Kate Hayes' Hill, and near the Empire mine, intend starting up work this season. The mine has upon it good hoisting and pumping works, and a two-compartment shaft sunk to the depth of 235 ft. These improvements were made two years ago by the Menlo Company, an eastern incorporation, that bonded the mine for \$40,000, but owing to the complications with other mining ventures in Utah, the company was compelled to suspend operations.

RICH GRAVEL STRUCK.—Nevada Transcript, Jan. 28: Some very rich gravel has been found in the

hydraulic mine of John C. Murchie, Sr., near town. We are told that previous to the Sawyer decision \$800 was washed out from a very small block of ground. Skiff and William Murchie will try the experiment of drifting the channel. If the gold continues as heavy and plenty as it is in the present face of the bank, the labor will prove profitable.

RICH STRIKE.—A strike of unusual richness was made in the Franklin mine, owned by Hussy & Hussy, at Willow valley. A blast in the face of the incline uncovered a fine body of ore, from which many exceedingly rich specimens were taken. From three tons of rock were selected three candle boxes of specimens, which it is estimated are worth at the rate of \$5,000 per ton. The ledge is 17 inches wide, well defined, and the general indications are most flattering, giving evidence of permanence and continued richness.

Plumas.

AN IMPORTANT STRIKE.—National, Jan. 27: The foreman of the men employed by the Eureka Co. in running a tunnel in the Halsted mine at Rich Gulch, was in town on Wednesday, and reports that the tunnel has tapped the ledge, being a little over 300 ft in length. The tunnel has only progressed in quartz about three ft, but everything indicated a strong vein, and it will probably be 20 ft to the opposite wall. Gold was found in every horn-full, but no very rich prospects had been obtained when he left. Mr. Johns, of Eureka, has been telegraphed to in regard to the developments, and it is thought that he will be here before long to take a look at the mine. The indications are that the company will take it, and if so a very important mining camp will be started at Rich Gulch, and another summer will see the old East Branch coming back to the life, bustle and prosperity which it enjoyed in the "good old times" of thirty years ago.

THE PLUMAS EUREKA.—From Surveyor Keddie, who was up at the Eureka Hill last week, we learn that the mine prospects are very encouraging, and that the ledges look better than they have for several years. A fine body of ore has been opened by the lower tunnel, and the "header" is now in good rock, with a good prospect of having a large pay-chimney in front. Another good body of ore is also being worked in the old '76 mine, now a part of the Plumas Eureka. Heavy hoisting machinery will be put in the lower tunnel, and the rock will be raised from a considerable depth.

DIRECTORS.—Greenville Bulletin, Jan. 24: A new board of Directors has been elected for the Plumas Consolidated mine, and there is a probability that work may be resumed there in the Spring. No new discovery has been made in the Lucky S mine, nor any other ledge found than was known from the first. In the drift from the tunnel the edge opened out sooner than was expected, the pitch being greater than had been estimated. The vein on last Saturday was three feet wide, and the ore richer than any before found in the tunnel. Progress with the drift is slow, as the rock does not blast out well.

THE BIG STRIKES.—Inter-Mountain, Jan. 26: On the 500 foot south level of the Lexington the ore shoot mentioned in these columns is opening up magnificently. It has now been explored for a length upwards of 200 feet and is found thus far to have a uniform width of six feet. "Cold blooded" samples across the face of each drift show it to carry over sixty ounces and the pulp assays in the mill give the same result. Considering the extent of the shoot it is one of the richest ever discovered in the Butte district and proves the correctness of all the reports thus far made on the permanence and value of the Lexington ore bodies with the attainment of depth. In the Mountain View an important strike has recently been made in the north 300 foot cross-cut, where on the foot wall of the north ledge a considerable body of good copper ore was discovered. One streak, which is more than a foot wide and is strong and compact, assays forty-two and six-tenths per cent. copper and \$20 in silver. On either side of this streak is good concentrating ore. On the 400 foot level the south crosscut has just tapped the ledge, which has so far been penetrated but a few feet. The strike in the north 500-foot crosscut is regarded as very important and sets at rest all doubt as to the presence of copper in that locality.

San Bernardino.

IVANPAH.—Cor. San Diego Union, Jan. 23: Ivanpah is situated in Clark mining district, San Bernardino county. Fenner, on the Southern Pacific Railroad, about 80 miles distant, is our nearest railroad station, from which point we get our supplies; also a tri-weekly mail. The Ivanpah silver mines were discovered in 1869, since which time they have been worked constantly. There are two mills here, a five stamp and a ten stamp mill. The former is owned by Julius Jacobs, of San Francisco, and the latter by your correspondent. The mines that are now being worked are the Lizzie Bullock, Nos. 1 and 2, Stonevall, Beatrice, Monitor, Eugene and Commercial. The silver mines here are not very large, but very rich—probably the richest average of any district on the coast. At the northeast of the silver mines, and about a mile distant, are some large and promising gold mines owned by Jones, Taylor & Co. Application has recently been made for a patent for them, and they will doubtless be worked at no distant day. At the north of us a few miles, just in the edge of Nevada, are some large lead and copper mines, among which is the old Potosi. I am told that George L. Centre, former Supt. of the Cerro Gordo mines, a well known mining expert, says this is the largest and best lead mine yet discovered on the continent. The mine carries some 15 ounces in silver to the ton. There are near this mine other lead mines not so large as the Potosi, but carrying more silver. At the south of Ivanpah, and in Clark's district, are some large copper mines, among which are the Copper World, Nos. 1 and 2. This group of mines would furnish a railroad a large amount of freight, as also would the Potosi district. Mine owners here are watching the progress of the California Southern Railroad, hoping it will come through this district. There is no place on this coast where so much base metal can be produced within the same circle as Ivanpah. Millions of tons are awaiting transportation.

Sierra.

GRAVEL.—Sierra Tribune, Jan. 26: The Table Rock gravel claim is located about three miles south of Howland Flat, and adjoins the Bonanza and Virginia claims. Fifteen men are employed at the mine under the superintendency of P. Dorsey. The

dumps are filled with fine appearing gravel. Washing will begin whenever a sufficient supply of water comes. At the Sunnyside gravel claim, located near Bunker Hill, a contract to run 150 ft of tunnel was recently let. The contractors have completed about 50 ft of the contract. The company expect to have to run about 200 ft further after the completion of the present contract before the pay channel is reached.

RESUMED WORK.—Messrs. Uren Brothers & Eldridge are preparing to resume work on the Rising Sun gravel claim, formerly bearing the name of Thompson's ranch claim, located a short distance west of town. A tunnel, which has been run a distance of 700 ft, was found to be above the channel. Another tunnel was run 160 ft at a still lower depth, but had to be abandoned owing to the quicksand encountered. The owners now propose to start a tunnel about 200 ft lower down the hill, from where it is believed that the lead can be successfully worked. From a shaft sunk in one of the tunnels, excellent prospects were obtained. The gold is of a coarse character, one piece found weighing half an ounce.

A MINE ALREADY PROSPECTED.—The Chipp's Flat mine is located about one and a half miles above town, and is owned by John Henderson. An eight stamp mill is built on the property. A tunnel was run on the ledge a number of years ago, and the upper portion of the mine was worked out at a good profit, the ore yielding as high as \$30 per ton. The present owner started a tunnel that will tap the vein in 700 ft at a depth of 200 ft below the old workings. Owing to the hard rock encountered in this tunnel, Mr. Henderson has found it necessary to abandon work for the present.

GIVEN A NAME.—The rich quartz ledge recently located near Deer lake by Messrs. Busch, Sanderhaus, Deidesheimer and Hughes, has been named the Young America. A tunnel was started on the vein to-day that will permit of its being worked to a depth of 200 feet.

THE BONANZA QUARTZ CLAIM.—The Bonanza claim is located a short distance above the Marguerite mine, near Loganville. A tunnel has been run on the ledge a distance of 75 feet. Forty feet of the tunnel has just been completed by contract. The vein has an east and west course, running parallel with the Marguerite ledge.

THE SIERRA BUTTES MINE.—A scarcity of water for milling purposes compelled the temporary discharge of a portion of the men working in No. 6 and 7 tunnels of the Sierra Buttes mine to-day. Work at the two lower tunnels will be continued with a full crew. In the meantime every effort is being made to get the new mill, at No. 9 tunnel, in running order as quickly as possible, as a sufficient supply of water can be obtained from the lower levels of the mine to keep that running. The managers are making the most of the present fine weather by pushing ahead work in an energetic manner on the outside. The ore-bin at No. 8 tunnel is nearly completed and the tramway to run from there to the mill is well under headway. The tunnel under the road, from the terminus of the tramway to the mill, a distance of 200 feet, is completed.

Tulomme.

ORE.—Union Democrat, Jan. 26: M. A. Hyde is getting the one stamp mill at the Golden Treasure mine in condition to start up. He has a quantity of ore on the dump, and plenty more in sight in the mine. Recently he had a small lot worked at the Patterson mill, which gave a return of \$62 per ton in free gold. In addition the ore is very rich in high grade sulphurets.

RICH STRIKE.—Independent, Jan. 26: App & Co., on Quartz Mt., came across a little vein of quartz on the surface in the main road, a few yards south of Whitney's store, which is literally alive with gold. Our informant states that there is at least \$20 to the pound of quartz. Thousands of men have lived and boarded around Whitney's while engaged on the extensive mines there, and the road has been traveled ever since the days of '49—and this hidden treasure is only just revealed. Scratch Tulomme on the back almost anywhere and you will find gold.

NEVADA.

Comstock District.

SIERRA NEVADA.—Enterprise, Jan. 26: The raise from the 2000 is now fast nearing the 2700 level. This connection will so change the draft and give such a circulation of air as will permit of the prospecting of several streaks of ore known to exist in the mine to the northward. On the 3100 level the northeast drift is of ore which is quite rich in gold. This streak varies in width from day to day, but is liable to lead to a deposit of value, as there are other streaks passed through in the joint Union Consolidated crosscut that are liable to be cut by this drift to the northeast. Several of the streaks already cut would pay well for working were they not cut up by many thin sheets of barren porphyry.

HALE AND NORCROSS.—The winze below the 2700 has now reached the 2800 level, and a sump is being sunk below that point. As soon as the sump shall have attained a proper depth, the work of opening a station and exploring the 2800 level will be commenced.

GOULD AND CURRY.—The Bonner shaft has been put in good repair down to the 1200 level, and the north drift is now being cleaned out and repaired up to the Consolidated Virginia line.

UNION CONSOLIDATED.—The same good progress continues to be made in the two drifts that are now approaching each other on the 3100 level. The two will soon be connected, when prospecting may be prosecuted at several points where ore is liable to be found.

ALTA.—Good headway is being made in the main east drift on the 2150 level, which is being pushed for the ore deposit as rapidly as possible. The west crosscut on the 2150 level will soon be cleaned out, when explorations will be continued in the vicinity of the west wall.

BEST AND BELCHER.—The ground in the bottom of the joint Gould and Curry winze below the 2500 level is still very soft, and requires close watching and close timbering. There is some water, but it does not materially interfere with the work of sinking.

MEXICAN.—General repairs are being made in all the levels from the 2500 down to the 3100, and

when the connection in the Union Consolidated is made and a good supply of air obtained, prospecting will be commenced at several points.

COMINATION SHAFT.—The new hydraulic pump, the air compressor, and all the other machinery, is now doing excellent work. Sinking for the 2800 level has been resumed, and the shaft will be pushed down to that point without delay.

OPHUR.—On the 150 level they are still extracting a considerable amount of ore, and besides are doing a great deal of prospecting.

CROWN POINT.—Owing to the low stage of water in the Carson river and the freezing up of the wheels of the mills, but a limited amount of ore is being extracted.

YELLOW JACKET.—All the ore that can be reduced at the mills on the Carson river is being extracted, and some prospecting work is being done.

UTAH.—On the 1750 level the northeast drift is making rapid progress in quartz that is beginning to give very promising assays.

Columbus District.

MAKING REPAIRS.—*True Figure*, Jan. 26: A force of eleven or twelve men has been engaged for the past week in repairing the lower mill of the Northern Belle company at Belleville. The entire machinery is to receive a complete overhauling and will be put in first-class order, but for what purpose, or what ore will be crushed, many inquiries develop not. At any rate it is gratifying to see the air of activity given Belleville, and its inhabitants are, for the time, contented.

ABOUT READY TO RESUME.—The new engine foundation at the Mt. Diablo hoisting works is finished and ready for the engine, which was sent to Carson for repairs and arrived here by last night's train. It will not be many days before the whistle at the works will add its melody and it is melody in a mining camp—to that of the Columbus Consolidated, and the work in the mine be resumed.

THE COLUMBUS CONSOLIDATED.—The main shaft has been sunk about 65 feet below the station of the third level, making a total depth of about 375 feet. The drift from the shaft on the third level was extended about 5 feet during the week, making a total length of about 40 feet. The rock in this drift still continues to be very hard. The drift from the bottom of the Bonanza winze, running to connect with the shaft on the third level, has been extended 10 feet, making a total length of about 90 feet. The face of the same still continues in broken up vein matter yielding fair assays. The crosscut running south from the lateral drift on the 150-foot level has attained a length of about 90 feet. It still continues in broken vein matter giving fair assays. Since the date of the last report there has been no material change in the work on first level. The work of extracting ore will be resumed as soon as the third level connection is arrived at. A new road is now being made to enable teams to go to and from the ore, which will be completed in a short time.

AN OUTSIDE OPINION.—Much speculation is being made by parties, in fact everybody in the towns of Candalaria and Piekhandle, as to what will be done and when, toward the resumption of work in the Northern Belle and Holmes mines, the former particularly. The editor of the *Hawthorne Bulletin* has been interviewing some of our merchants and says it was ascertained that the boom was not expected to reach the town before summer, but that when it does come Candalaria will be livelier than ever before. It is expected that the Northern Belle assessment will nearly all be paid, as its principal stockholders own about one-third of the Holmes stock, and will get their money back when the judgment is paid. Companies having money on hand intend to spend it in development work between now and July, and there is talk of a new leaching mill.

Eureka District.

BRIEF NOTES.—*Eureka Sentinel*, Jan. 25: The Colorado mine, for a long time lying idle, is now being worked with good chances of developing into a very productive and valuable property. It is owned by J. E. Jones, Herbert Davis, Griffith Jones, John Williams and John Evans, who are preparing for a season's work. They have a four-foot vein of ore and ledge matter to start on. The southerly portion of the mine was leased some time ago to John McNaughton and one of the Laird brothers, who have already shipped 30 tons of ore to the Eureka Con. furnaces that worked \$102 per ton. They have 40 tons of the same kind now on the dump, as well as considerable more in sight in the mine. Roberts Brothers have put up a patent Baker iron wharf at the Pentier mine, which works splendidly. The incline shaft is down 130 feet, and from the 80-foot level a drift, now in 60 feet, will be driven 40 feet further to the center shaft, which it will tap 160 feet from the surface. At the bottom of this shaft is an abundance of ore, which goes from \$100 to \$160 per ton. A contract has been let to P. F. McBride to run 50 feet of drift to the Connolly mine. Pat thinks there is a good showing for a nice body of ore in the vicinity of the drift. The question of building a refinery is being discussed by the Eureka Con. Company. It will have work for a long period in refining bullion obtained from the company's mammoth slag pile alone. The Grant mine will be worked in part for flux quartz ore. The ore from this mine is usually very rich. The Hamburg tributaries are still working successfully, and new pitches are being taken. Jo. Molino is taking out some good ore from the Altoona mine on Adams Hill. Prospects are improving in the Uncle Sam Con. mine on Peeltick Hill.

Patterson District.

THE NEW DISCOVERY.—*White Pine News*, Jan. 26: Our Hamilton correspondent sends us the following concerning the new mining discovery in Patterson District: Some time since Mr. Flowers, formerly of the Truckee mine, went out there and found the appearance of the locality quite favorable for mineral in his opinion. They went to work in a small open cut, which is by itself some distance up the mountain from where most of the original workings were made. With but little labor they found only a few feet to the left of the original cut, and almost upon the surface, the pocket or ledge—which ever it may be—that they are now in. They are still engaged stripping the deposit, without having reached its terminus. It is pitching downward, and they expect after a few feet further to go under the surface, which will be a great advantage at this severe

season. Mr. J. B. Mathewson and Col. Conter have been out there and speak favorably of the new find. C. A. Mathewson and Thomas McKinney are now making a prospecting visit there. Assays from samples of the ore brought to Hamilton, range from \$100 to \$1,484 per ton, the former sum being the lowest of any made. The mine is about one mile up the mountain from the original town site of Monterezuma, three miles from the now traveled stage road and nine miles from Parker's Station. The discoverers think they have a good thing, and everyone in this section will rejoice if such proves to be the case.

Tuscarora District.

INDEPENDENCE.—*Times Review*, Jan. 24: There is a slight improvement to note in the workings during the past week and the usual progress has been made in extending the drifts and crosscuts.

NORTH BELLE ISLE.—The tributaries on the upper levels are extracting some good ore.

ELKO CON.—Have resumed work on the main west crosscut, 200 feet level. North drift has advanced 10 feet, south drift, 8 feet.

GRAND PRIZE.—South drift on the 500 foot level, is in 111 feet—ledge is poor. Have been putting in new track in the 400-foot level, and will soon resume work in the south drift. Also in the north latera the 300-foot level. Mill is shut down.

NAVAJO.—The usual progress has been made with the work at all points. The stopes of the different levels are without material change. The usual amount of ore has been extracted and sent to mill during the past week.

Ward District.

PROSPECTS.—*Ward Reflex*, Jan. 24: Our mining prospects never looked better. The Argus has put on a full force of men and the mine is yielding splendidly. Twenty tons of ore per day are hauled to the mill for reduction, and I have been credibly informed that the ore works highly satisfactory. The Monitor Company has sunk to the depth of 105 feet, and ore at the bottom has been assaying from \$30 to \$100 per ton. R. M. Peters and John Morgan, after becoming satisfied with having struck an ore body dipping into the hill on the Hayes ground, have gone back about 100 feet and started a shaft. The indications are that the company will ship five bars in a day or two—its first shipment.

ARIZONA.

MINING MATTERS.—*Prescott Courier*, Jan. 24: The smelter, at Howell, twelve miles south of Prescott, is running. The Belle mine, which has, so far, furnished abundance of ore for this smelter, looks as if it will continue to do so for many years to come. Carr's freight trains are stretched out, hauling bullion from United Verde and coke from Ash Fork. There are at the smelter upwards of 200 tons of bullion.

NOTES.—*Pinal Drill*, Jan. 26: In the Last Prize they report a big strike. The First Chance is under steady work by the owners, Beach and Taft. They are sinking a winze in the Tunnel. The Eureka is again under headway. Mr. Wheeler has let a contract to sink one of the shafts 50 feet deeper. The Australia shows up good metal. They are drifting into the Mountain from the bottom of the shaft which is 85 feet from the surface. The vein is 3 feet wide in mineral. The Worldbeater sends a considerable quantity of rich ore to the "Pinal Reduction Works." The Pinal Reduction Works are busy pulverizing and concentrating. Everything works well. The building around the machinery is progressing. Double adobe walls are going up fast. The foundation is of stone and the roofing will commence as soon as the walls are finished. The teams are busy hauling ore. The Speciepaying is progressing with its mill. The road from the mine to the mill is completed. A large amount of work is now going on in various mines by the owners. They are taking out ore, for what there is in it, with a view of selling or having it worked at Pinal. The Silver King artesian well is continually gaining depth under the heavy blows of the immense plunger.

BISBEE.—*Tombstone Epitaph*, Jan. 27: There is an increased activity noticeable in this part of the country such as has not existed since the earliest days of the great copper camp.

COPPER QUEEN is going on in its usual even tenor. The stopes on the 200, 300 and 400 levels are in splendid condition, easily turning out their regular amount of ore. Some little trouble is at present being encountered by the settling of the timbers on the lower levels; the ore being in such a soft formation that the tremendous weight of ore and dirt to be supported requires the heaviest of timbers, and even these in many places will have to be bulkheaded up solid with square timbers. The furnaces are doing remarkably fine work, and turning out their regular shipments of bullion.

SILVER BEAR.—This company is sinking a well near the New York mine to obtain water for the smelter, which will be erected in a short time, as soon as Mr. Brown, the manager returns from Kansas City, where he is now in company with Judge Duncan, of the New York mine.

GALENA.—Work is being vigorously prosecuted on this mine, which is developing to the perfect satisfaction of the owners. Several tons of very fine ore have already been taken out.

BROAD GAUGE GROUP.—Work is to be resumed at once on this property. The principal amount of work will no doubt be done on the Broad Gauge mine. As that lies a little to the southeast of Holbrook, and the ore body running through the latter leads right into the Broad Gauge, there are several other properties about Bisbee on which work will doubtless soon be resumed. Some prospecting is being done in the mountains this side of Bisbee, and quite an important strike is reported in the Bunkum mine, some six miles this side of the town. The ledge is several feet in width, and the ore, which is of a free-milling character, assayed from 60 to 120 ounces silver per ton.

WEST SIDE.—*Tombstone Epitaph*, Jan. 27: The ore bodies recently found on the 500 level are developing very favorably, the ore being of a very good grade and easily mined. The stopes between the 300 and 400 levels and the 400 and 500 levels are looking remarkably well, and are turning out their usual amount of ore.

LUCKY CUSP.—This mine, which is also the property of the T. M. & M. Co., is being worked by three different shafts, and turning out a considerable

quantity of manganese ore, which is used at the furnace with other ores to very good advantage.

EMPIRE.—This mine is rapidly coming into prominence as an ore producer. A large amount of ore has already been broken from the new strike on the 200 and 300 levels, the old ore dump has been cleaned up, and the hoisting of ore from the 200 level will commence to-morrow.

HEAD CENTER.—Work was resumed in the north workings of this mine last Monday.

GRAND CENTRAL.—The pumps are still running at full capacity, and are steadily but surely gaining on the water. The stopes from the 500 level up to the 100 level are looking well, and continue to easily produce the daily output of 85 tons. This keeps the mill running at its full capacity; and there is ore enough now in sight to keep it running for many months to come without further developments.

RAILLENSAKE.—The company's mill at Water-vale has been shut down for a few days, but will start again on the first of February. Meantime prospect work is being pushed at the mine. During the past week fine ore bodies have been discovered in the Bunker Hill ground, adjoining the Mammoth's.

COLORADO.

IMPORTANT CONSOLIDATION.—*Georgetown Courier*, Jan. 26: The filing for record on Monday of certain conveyances completed a mining consolidation on which our reporter has had his eye for many months. It is no less than the transfer of the valuable properties of the Silver Plume Consolidated Mining Company, on Republican and Sherman mountains, to the Consolidated Pay Rock Company, which taken has, under Superintendent Egan's management, been steadily extending its work of development and output for several years. The successful completion of the Pay Rock Concentrator last Summer provided a means of utilizing the vast reserves of the company's low grade ores, and it only remained to effect the present consolidation to secure for this company undisputed possession of a group of the most valuable and extensive lodes in this end of Clear Creek county. To Superintendent Egan's quiet negotiations for 18 months past, is due the attainment of this end. The two companies were involved in expensive law suits over the territory now deeded, the issue of which no man could foresee any more than could he anticipated the new and embarrassing complications likely to ensue. Last Summer Messrs. Havelman, Platt and Washburn, Boston and New York capitalists, and large Pay Rock stockholders, visited the mines, grasped the situation, and energetically adopted Mr. Egan's scheme of consolidation, which was also actively pushed by State Geologist Foster, Superintendent of the Silver Plume Co. By this the Silver Plume Company conveys to the Pay Rock Company, the Silver Star, Bernice, Silver Plume, Hopewell, Hickman and College lodes; the litigation between the Hopewell and Hickman lodes, on the Plume side, and the Santry and Zouave, on the Pay Rock, is ended, and the title of the latter company secured beyond all future assault, the patent to the last named lodes now going through in regular course. As a consequence, active and extensive development has been resumed, which must soon result in large and rich mineral exposures.

WORK.—*Georgetown Courier*, Jan. 24: Allen Bros. commenced work on the old drift of the Cataract lode last Monday. They have struck a splendid streak of ore in the stope, which assays 384 ozs. per ton. John Conway & Co., lessees on the Little Emma, on Democrat mountain, brought down over four tons of ore this week, which ran 551 ozs. silver per ton, all in one class. This is the result of one month's work. Geo. A. Cole brought down 132 sacks of ore from the Bismarck Tuesday. There is a streak of ore in the stope varying from 2 to 6 inches in width. There is quite a good showing in the heading of the No. 3 adit. About 60 men are employed on the 730 mine. Seven drifts are now being run, six of which are in mineral. There are two miles of drifts and winzes in the mine. About 1317 feet of drifting was done last year. More powerful machinery will soon be added. Dean Bros., lessees on the Alabama, on Leavenworth mountain, struck a 6-inch streak, which will probably assay 2,000 ozs. silver per ton. We were shown a specimen of the ore, which is sulphurets and gray copper, and it is as fine as we have seen for many a day. Mr. Frank Hartzell, Superintendent of the Moline Tunnel Company informs us that the company has decided to push their tunnel ahead, regardless of every other matter. There is a belt of rich lodes ahead of them, and they realize that their interests lie in opening them at a great depth. Work will be resumed about the first of next month. Sometime during the spring, an air compressor and another Ingersoll drill will be put in operation. The tunnel is now in 600 feet.

IDAHO.

EXTENSIVE.—*Ketchum Keystone*, Jan. 24: The mines of East Fork of Wood river supply sufficient traffic to Wood river towns to keep that vicinity accessible by a well packed sleigh road. Mining operations hereabouts are three times more extensive than during the winter of '82 and '83. Then winter work was a thing unapproached, and there were scarcely any teams retained for hauling after the first snows. Now the Ontario, Elkhorn, Parker, and several other properties carry on their usual summer work, and employ teams steadily to and from the smelters. Two four-horse teams fly between the Elkhorn and the smelters on second-class ore, hauling as much as 2,000 to the animal at each trip. The Parker lode has become one of the best mines in the Elkhorn vicinity, and is doing more solid work than at any time previous. The ore is abundant and high grade. Ten tons were recently sold to the Bailey Sampling works for a net cash price of \$2,300. The result of two men's labor in the past thirty days has been fifty tons of this quality of ore, and the proprietors are now shipping the same to the sampling works. There are four teams hauling from the mine steadily.

DOWN FROM THE PARKER BONANZA.—*Wood River Times*, Jan. 23: E. H. Terry, one of the owners of the Parker bonanza, came down from Ketchum to-day. He says that besides the 50 tons of ore which is being shipped from the mine just now, there is at least fully as much more in sight, and there is only a hole on the ledge so far. Mr.

Gillenwater recently sold a fourth-interest for \$15,000 cash, and there is a standing offer of as much more for another fourth, but none of the owners want to sell.

THE RISING SUN.—*Wood River Times*, Jan. 23: The Rising Sun mine, of Bullion, has just been sold to G. D. Mackey, and other New York capitalists. The price paid is \$15,000 cash, and about one-half of the capital stock of the new company. The former owners of the Rising Sun were Michael Hynes, who owned three-fifths, and Dr. S. B. Miller, who owned two-fifths. The money to pay for the mine came yesterday, and the new company will begin work at an early day, with Mr. S. B. Miller as manager. The Rising Sun mine is situated in the Bullion mineral belt, and is believed to be a very promising mine.

NEW MEXICO.

THE SMELTER.—*Rio Grande Republican*, Jan. 26: The Smelter started up on Tuesday. The run was intended to be a trial one, and was, to a certain extent, a success. The galena smelter was started first, on ore from the Crescent City, and in due time a run of bullion was made. The copper smelter was then started up, also on galena ore, but the blower which did pretty well for one furnace, was not strong enough for two, and the metal soon froze up. The galena smelter made a good record, and would probably be running yet, but that the pipe which admitted cold water to the water jacket was too low down, and the cold water chilled the metal. It is now raised, and on Monday night the galena smelter was fired up again; the copper smelter being allowed to lie idle. The successful running of the smelter, which now seems to be placed beyond question, with the exception perhaps of a few trifling alternations or changes from time to time as experience may point out, has put everybody in Organ in good spirits, no one now has any doubts as to the grand future before the camp, and that too in a very short space of time. Unless something very unexpected happens, next summer will see Organ a camp second only to Lake valley. The number of buildings going up, and the amount of business being prepared for, is evidence at least that the men who have money to spend are convinced that there is a bright future before us. We do not say this to induce store-keepers and whisky-sellers to flock into Organ. We have enough of them here now. But there will soon be a demand for miners and laborers that will give employment to all who may come.

ORE.—*Silver City Enterprise*, Jan. 25: The last of nineteen cars of high-grade ore and concentrates was shipped Wednesday by M. W. Bremen to the Socorro smelter. The output from this property will make a splendid showing this year as it did last. Wolcott & Mills departed for Denning Wednesday, from whence they will take a carriage for Tres Hermanas to examine the new strike of lead carbonates made by one Carter, and in which they are interested. The strike is said to be the best yet made in Tres Hermanas district. A one-eighth interest in the Pennsylvania mine in Steeple Rock district was purchased by Nate Scarritt and John A. Moore on Saturday, of Doc Kane. The price paid was \$350. The claim is one of great prominence and we learn that work will shortly be commenced upon it on an extensive scale. A large body of water has been struck in the Bonny Jean mine, at Shakspeare, at a depth of 300 feet, and the Superintendent, Mr. Allan McLane, has gone to St. Louis to purchase pumping machinery for the mine. Aside from the recent floods of water, the mine is looking well. From the Yellow Jacket mine, an extension of the Cincinnati, in Tres Hermanas district, two car-loads of ore that sampled eighty ounces per ton were shipped this week. This camp promises to make a fine production of bullion during the present year.

THE SOLID SILVER company has received returns from 6200 pounds of Black Hawk ore, shipped some time since. 840 pounds of this shipment was native silver, which flattened on going through the stamps and came out in solid chunks, which averaged 80 per cent. pure silver. The balance of the shipment, 5360 pounds, netted \$19,343. The Colorado smeltering people say that it is the richest ore they have ever treated.

OREGON.

ITEMS.—*Jacksonville Times*, Jan. 26: Rough weather for miners. Several persons in this section prospecting for quartz. Isaac Skeeters is pipping night and day on Hogue Hill, Josephine county. Piping is going on in the Steamboat district, notwithstanding the frosty weather. Little snow is in the mountains now, the warm weather of the past fortnight having melted it off. A prospector employed by Fuller & McNulty, has discovered on the Siskiyou what promises to be a good quartz ledge. There is said to be plenty of free gold in the rock. The miners of Josephine county are all busy. There are as many as five giants at work in a circle of two and a half miles. Several old miners are coming back to the mines, there to hunt old claims they worked several years ago.

UTAH.

NEW SANOSTONE DISTRICT.—*Salida News*, Jan. 22: Mr. George H. Harlow, returned last night from a visit to his mines at the Lower Crossing of the Denver & Rio Grande, in Utah. He says the excitement is intense over the recent discoveries, and that the people are rushing in from all sections. A new town has been laid out, named "Summerville," and lots are selling fast. The mineral belt is 15 miles in length with ore that gives assay returns of 30 per cent copper and 63 ounces in silver. Mr. Harlow has three valuable claims located in the best part of the district, on which he has a force of men at work. He is also interested with Messrs. H. Sherwood, C. P. Crozer, and I. E. Arnold, in ten claims in one group, located by Mr. Arnold on a recent trip to that section, as an expert. Mr. Harlow examined these properties and expresses himself as greatly pleased with their location and the surface indications. Considerable work in development on all these claims will be done this season. Information was received in Salt Lake yesterday that a company had been formed in Chicago for the purpose of developing a group of ten mines recently purchased in this district, and that work would begin immediately.

For Mining Shareholders' Directory, Stock Reports etc., see page 97.

The Big Drum Lummon Mine.

A reporter of the *Helena Independent* has interviewed Mr. George Attwood, general manager of the Drum Lummon works and mine, now known as the "Montana Company Limited," and elicited from him much interesting information. Mr. Attwood is a gentleman of very pleasing manners, frank and courteous, and seemed disposed to give all information concerning the valuable property in his charge that would be of interest to the general public. From him we learned that the five-stamp mill of Mr. Cruse's has been increased to ten stamps, and is now running regularly, crushing about ten tons of ore per day. The product from this little mill is some \$15,000 per month in gold and silver, the gold comprising over 50 per cent.

Mr. Attwood also informed us that he has about four hundred men employed in erecting the mining machinery and building the new mill, which he expects to get into running order within the next two months. The mining machinery will be in operation inside of two weeks. The power of the mill—300-horse power—will be sufficient to run fifty stamps; but only twenty stamps will be started at first. Thirty more, however, will be added immediately afterwards, and Mr. Attwood estimates that the whole will be in operation within the next three or four months at furthest.

The capacity of the twenty stamps soon to be running will be forty tons per day—two tons to the stamp—and when the mill is completed it will crush 100 tons per day, or 110 tons per day including the product of the ten-stamp mill now in operation.

The ore crushed has averaged in gold and silver to the ton about \$75, so that the daily yield of the 110 tons crushed will be over \$8,000 per day, or \$2,880,000 for 360 days.

The Outlook of the Mine

Was never better than now. The lead, 80 feet wide, has no waste rock, and, as stated, averages \$75 per ton as it comes from the mine. Mr. Attwood has caused a shaft to be sunk fifty feet in depth in the lowest level of Mr. Cruse, and finds that the ore is richer at that depth than above. This is exceedingly encouraging and naturally leads to most sanguine anticipations of what will be struck in the lowest level, now being pushed rapidly to completion. This level has now been driven into the mountain 900 feet, and is steadily advancing through solid rock at the rate of 120 feet per month. It is wide enough for a double track and seven feet high, exclusive of the timbers, water way, etc. Mr. Attwood confidently anticipates that he will strike the lead and unearth its vast treasures within the next sixty days.

This level or tunnel has been called the Maskelyne Tunnel, in compliment to the President of the company, the Hon. Nevil Story Maskelyne, who is a member of the British Parliament.

At the mouth of the tunnel Mr. Attwood has erected the most

Complete and Extensive Mining Works. To be found in the West. It consists of boilers and engine with 200-horse power, which will be utilized for driving the stopping drills in the upper tunnel, including the mine pump, hoisting machinery and ventilating fans, as well as for driving the drills in the deep tunnel and ventilating the same.

Among other improvements should also be mentioned a tramway to carry the reserves of ore from above the Cruse tunnel to the new mill. This is a substantial inclined way traversed by iron cars, and having a capacity of two tons to the car. At each end of the tramway are ore bins having a capacity of thirty tons each.

We learned also from Mr. Attwood that his mine plant consists, in addition, of a sawmill driven by a 15-horse power vertical engine; also a large lathe driven by a 10-horse power vertical engine; also a planing machine, bolt and pipe cutter, blacksmith forges, etc., all inclosed in a massive building 107 feet long, 61 feet wide, and 44 feet high. The machinery will be utilized not only in the construction of the works, but in keeping them afterwards in repair.

It is difficult at this time to estimate the immense value to Helena and Montana of this mine. Mr. Attwood thinks that from

Four to Five Hundred Men

Will be kept constantly employed by this company in the mine and mills, and as many more will incidentally find employment in various industries produced by the enterprise, such as cutting and hauling wood, burning charcoal, etc., etc. The average wages paid by the company are \$3.00 per day to its employees, and those finding incidental employment will doubtless realize as much—making a grand total of about \$3,000 per day which will go into the hands of laboring men, and from them pass into the various avenues of trade. This equivalent to \$1,100,000 a year for labor alone, saying nothing about the large amounts which will be expended in other ways by the company. Assuming that the lower tunnel finds the vein of the same richness and width as above, of which there is but little doubt, it will develop a block of ore 250 feet high and 80 feet wide. The mine has been prospected by drifts along the vein to a distance of 800 feet, and assuming that this is all there is of it, we obtain the number of cubic feet by multiplying the height, width and length together. Thus 250x80x500 equals 16,000,000 cubic feet. Twelve solid cubic feet of ore represents a ton, and dividing the 16,000,000 cu-

bic feet by twelve, we have 1,333,333 tons of ore above the lower level. Estimating that 100 tons of ore are crushed per day, we have say 36,000 tons per year, and at this rate it would require 38 years to crush the ore in sight above the lower level, to say nothing about the balance of the lead! Our readers may set it down as a fixed fact that if the lower tunnel finds the lead as good as above, the Drum Lummon is the greatest mine in the world. Helena has reason to congratulate herself upon its close proximity. The Wickes cluster of bonanzas and the Drum Lummon lead, would alone support a city of 10,000 inhabitants, saying nothing about our other resources.

Talk About Copper.

The history of copper mining in the United States during the past year is full of interest. The product of the Butte mines, says the *Inter-Mountain*, seems to have upset the calculations of the copper sharps, and the estimates made in '82 for the ensuing year have proved to be far out of the way. In our sister Territory of Arizona the effect of the Butte production has been most seriously felt, but the high prices which prevailed during the early part of the year sufficed to make the Arizona output much larger than it is likely to be for '84. That one mining region is made to prosper at the expense of another is to be deplored. Arizona has some magnificent copper properties. The ore, though carrying a less proportion of copper than that of the Butte mines, is much more easily extracted and reduced, being for the most part a carbonate and above water level; but it carries no silver, and the policy of the Atchison, Topeka & Santa Fe and the Southern Pacific Railroads is so extortionate that at the present ruling prices the copper mines cannot be worked to any degree of profit. Only one mine in the Territory—the Copper Queen—is able to make any sort of a fight against present antagonistic conditions.

The Butte mines have been continuously and successfully worked. When the market was glutted and Pope, Cole & Co. refused to purchase any further supply of ore and matte on account of inadequate facilities for separation, the Butte companies, with the exception of the Parrott, which largely consumes its own product in an Eastern factory, began shipping to Swansea, where a ready market was found at fairly remunerative prices, the Butte producers entering into active selling competition with those of Chili and Spain. One reason of this was the high percentage of copper contained in the Butte ores and matte, and the fact that they contained a large amount of silver, which greatly assisted in meeting the extra expenses of transportation. The silver value of the Butte copper exports may always be relied upon to furnish an important element of strength in competing with foreign producers of exclusively copper ores. The future of the copper industry of Butte may therefore be confidently stated to be exceedingly bright, with ample assurance of its so remaining.

In the American market the Lake Superior mines are Butte's only formidable competitors; but as the Lake product and the Butte product enter into different uses to a large extent it is reasonably certain that even if the foreign demand should decline, which it is not likely to do, the increasing consumption in this country may be depended upon to create a steady market for much more of the Butte product than is now sold in this country. Another reason for this belief is that many of the Arizona mines which have been largely contributing to the home demand will have to remain closed down.

In this connection the following review of the upper market for the year '83 and estimates of production, though somewhat inaccurate as to Arizona, may be of interest. It is taken from the circular of Mathews & Webb, samplers and ore buyers, of Denver.

Copper—The year opened with a very quiet but firm market, at 18 cents for Lake and 17 cents for less favorite brands at New York, but within two weeks the first large pool sale was made, being about 12,000,000 pounds at 18 cents, mostly to consumers at and for deliveries along over the first four months of the year. The Lake companies had agreed to sell for no less price over the time of deliveries, but from the day of the sale on the price was never any higher, and gradually sagged off, reaching 17½ cents by the middle of March, with a very general feeling that a break was inevitable. Early in April about 50,000 tons were sold for export, and immediately thereafter the price of Lake dropped to 16 cents, and even 15½ cents, at which prices, in varying firmness and weakness, the market drifted along until the early part of June, when it became evident that the various outside brands, such as Baltimore, Arizona, etc., were accumulating. Another export movement was freely talked of, but none occurred, and the demand increased so as to fairly absorb the supplies. Prices, however, continued to weaken slowly, from 15½ cents in July down to 15 cents until early in September, when the decline was checked and a trifling advance established and maintained until the middle of October, when a pool sale of some 8,000,000 pounds to manufacturers and dealers, at 15 cents, was made. From that time to the close of the year the price has ruled very steadily at and about 15 cents for Lake, and 14 cents to 14½ cents for the outside brands, and closes with the general

impression that copper is very near the cost of production.

The year's production is set down by the most competent authorities as follows:

	Pounds.
Arizona	35,000,000
Montana	38,000,000
Utah, Colorado, etc.	5,000,000
	78,000,000
The Lake regions	65,000,000
Total	143,000,000
Exports have been	26,000,000
Left for home use	117,000,000

Sonora Mines.

G. E. B. Durand has been interviewed by the *Eureka Sentinel*, and describes that portion of Sonora which is near the Chihuahua line and on which the Sierra Madre mountains are, as God's own country. He says the climate is delightful all the year round. Nature has done everything besides to make the region charming and attractive. The soil is rich, and almost everything grows luxuriantly and without much care. In the driest season of the year, streams brimming over with cold, clear, pure water abound, along the borders of which peach trees and watermelon patches, wherever there is a ranch, delight the eye and produce luscious fruits. The scenery is magnificent. He says: "If I should take you up on one of the summits of the Sierra Madre, and give you a good glass to look at the surrounding country with, it would excite you. You wouldn't be able hardly to talk about what you saw. That's the way the scenery affected me."

"As for mining, it is by all odds the richest section I know anything about, especially in copper ores, although I speak mainly with reference to the silver mines. I saw a specimen of ore that went \$1,000 in silver, and carried by actual assay 50 per cent of copper. You can travel about in a thousand gulches and pick up float rock, free milling, that will go from \$30 to \$40 per ton."

The Drawback.

"If miners could work in Sonora as they can in the United States, you would not see me here. The fact is, there you never can feel that either your property or your life is safe. Few prospectors can stand the expense involved in securing a title from the Mexican government, and even then you are subjected to annoyances, and, strange as it may seem to you, who are familiar with the sacredness of such a title in this country, you are liable to lose it. The way that you come nearest being safe in your possession is to have a native Mexican in with you as a co-owner. Then, ordinarily, you are secure as regards your patent rights. There are a few instances in which foreigners get along and make bullion out of the Sonora mines hand over fist. Near the place I mined there were two young Americans who struck a mine from which they have, with their own hands, been taking out between \$30,000 and \$40,000 per month for two years. But they have been very lucky in escaping the Indians, who are likely to shoot them through the head any day."

A NEW MINING DISTRICT.—Yesterday a gentleman by the name of Robert Waugh, from Eastern Iowa, who has been spending several months in the districts of Nevada, called at the *Tribune* office and exhibited some fine specimens of ore from Snively Mining District. This district was discovered late last October, and is eligibly situated three miles due south of Lory station on the Central Pacific Railway, about 16 miles west of Pilot Peak and 7 miles east of Toano. Some development work has been done on four locations, improving at depth. In one shaft 20 feet deep, 3 feet of excellent ore is exposed. This ore has been assayed in Salt Lake by McVicker and others, and runs from 39 to 2,100 ounces silver. Samples have been submitted to Prof. Clayton, who pronounces them fine. A full line will be sent to the Mining Institute, to show the world that Nevada has not lost its grip as great mineral producer. A. P. Snively, the discoverer of the district, is an old and experienced miner. He thinks he has one of the best districts ever found in Nevada, and is desirous that Salt Lake men visit it and examine for themselves. It is tributary to this city, and the development of the mines will not only enrich those who are first in the field, but will materially aid Salt Lake in retaining its position as the great mining center of the Rockies. —*Salt Lake Tribune*.

GOLD.—Snake river produces something better than fine gold in bottoms and shoals. Fifteen miles below the mouth of Dennet creek, near the mouth of Sturgis creek, there is a placer mining claim that is a good witness for itself. C. M. Keets, now of Mineral district, a practical assayer and miner, has shown evidence of the wealth of that stream by specimens of coarse gold that remind one of the mountains. They were taken from a claim owned by Wm. Tobin. Last fall, within a few weeks, \$1,500 was taken out of the claim—from a bar on the edge of Snake river. A half interest in the claim was then sold for \$1,000, and shortly afterwards two men washed out \$3,000 gold dust. They expect to take out \$6,000 next season. This claim is on the Idaho side of Snake river on the bar of the mineral belt extending across that portion of this county. —*Weiser Leader*.

The Colorado Mine Disaster.

A dispatch from Denver, Col., January 24th, says: "The explosion in the Crested Buttes coal mine this morning was one of the most appalling that ever occurred in a coal mine in this country. Crested Buttes, near which the mine is located, is a coal mining town thirty miles north of Gunnison City, on the Denver and Rio Grande Railroad. The explosion occurred either in chamber 1 or 2, just half an hour after the day force of sixty-seven men had gone to work. There were ten men at work in chamber 4, and these escaped unhurt, except one man, John Angus, who was in the passageway just outside the chamber. He is badly burned, but will recover. Fifty-seven men were at work in chambers 1 and 2. These, it is thought, have all perished. The explosion was of such force as to completely barricade the main entrance, and appliances for supplying air located near were badly wrecked and the roof of the tramway blown off. The men at work on the Anthracite Mesa mine, the night force of the Colorado Coal and Iron Company's mine, and citizens generally were working hard all day to rescue the men, although it is thought none can possibly escape alive. The Towu Hall has been prepared for the reception of the dead. As soon as possible the fan was repaired and put to work pumping air into the mine, and men were set to work to remove the obstructions so as to reach the chambers and get the bodies out to-night if possible."

Names of the Killed.

The following are the names of fifty-five of the unfortunate; the other two are unobtainable: Henry Anderson, John Williams, M. T. Stewart, John Martin, Thomas Rogers, Joseph O'Neil, Jacob Laux, John Anderson, James Walsh, Peter Baker, William Davidson, Richard James, David Hughes, P. McManus, W. L. King, John Creelman, John Hular, Thomas Williams, John Shan, Patrick Barrett, John McGregor, John Myers, F. W. Smith, G. B. McHelson, William Maroney, Nick Proist, Thomas Lailey, John Prince, James Driscoll, James Coughlin, Henry Stewart, B. Heffron, L. P. Heffron, W. L. Jones, John Donnelly, Carl Rodemauld, Charles Sterling, Thomas Roberts, James McCourt, Fred. Becht, Iker King, Joseph Weisenberl, H. Donegan, Joseph Krause, James F. Stewart, Jr., William Neath, Thomas Glancy, John Rutherford, William McCowitt, A. M. Godfrey, Daniel McDonald, William Aubrey, Benjamin Jeffries, Morgan Neath and Thos. Stewart.

Many of these are married and leave families, some of whom are living here.

Scenes at the Mine.

At this hour everything is in such confusion it is impossible to give details. A special train left Gunnison City at 2 o'clock this afternoon with surgeons and a large number of citizens to render all the aid possible. The town of Crested Buttes is in mourning, and crowds of women and children are about the entrance of the mine praying, wringing their hands and crying piteously, presenting a scene most heartrending. It is said that at the time of the explosion there were ten kegs of black powder in chambers 1 and 2, where the men were working and where the explosion is supposed to have taken place. The mine has three miles of drifting, and so it is impossible to definitely locate the accident until the rescuing parties gain admittance.

A Rich but Dangerous Mine.

The mine has long been considered dangerous by those acquainted with it. While one of the best producing mines in the country, its operation has always been attended with more or less apprehension and real danger. "It is a fire-damp mine," said Superintendent Cameron, now in Denver, "and there seems to be a constant drain of the most deadly gases; they seem to generate in the coal or under, and pour out in the seams of the walls, in the tunnels or shafts, yet the mine is one of the most perfectly ventilated in the world. Air is forced in along the shaft by machinery; no less than 56,000 cubic feet of fresh air is forced into the mine every minute. This is quite sufficient to supply the wants of the miners and keep the air perfectly pure unless some accident happens to cut off or interfere with the supply. This is a greater amount of fresh air than is furnished to any other mine in this country." Superintendent Cameron added: "We send a mine-viewer through every chamber each day before the workmen are allowed to go in. He must have returned this morning before the men started in, and everything must have been all right when he passed through the workings."

DR. DURAND says that the southern portion of Arizona is dull, but not more so than he finds Nevada to be. The mines there are mostly in lime formation, and easily worked. But little use is made of powder, and the expense of extracting ore with pick and shovel is so slight that \$15 ore in many places can be taken out with a profit. The country has been overdone, and a good many people who were induced to migrate thither on account of the stories of fabulously rich mines in the Tombstone and Tucson districts have gone out disgusted because they did not realize their expectations of immediate fortune. The reaction that resulted has put mining under a cloud.

Strontia.

Occurrences.

The strontia minerals have been identified at many points in the United States, and probably occur more frequently than is generally supposed, as systematic search for them has not been prosecuted to any extent. Strontianite (strontium carbonate) has been found at Schoharie, New York, in hydraulic limestone; at Muscalonge lake, New York; at Chaumont bay and Theresa, Jefferson county, New York; and in Millin county, Pennsylvania. Celestite or celestine (strontium sulphate) occurs at Green or Strout's island and North Bass island, Lake Erie, where it occurs in magnesium limestone of the Water-lime group, at the former locality being found in large masses of beautiful crystals; and at Chaumont Bay, Schoharie, Lockport, the Rossie lead mines, Depauville, and Starr, in the State of New York, and also at Bell's Mills, Blair county, Pennsylvania. The blue fibrous variety found in Pennsylvania is the celestite originally taken to Europe by Schutz and named by Werner.

Small lots of American strontia have been offered in the market from time to time, but have not always met with a ready sale.

Uses.

Nitrate of strontia is used in this country to a considerable extent by the makers of fireworks. It is made here by the chemical manufacturing works from imported carbonate.

An increased demand has recently sprung up in Europe, owing to the introduction of a new and successful process for treating beet sugar, which promises to absorb large quantities of strontia in comparison with the former consumption. Strontia has also been recently utilized in the manufacture of tuncres for blast furnaces. These new applications will undoubtedly lead to active prospecting for and mining of strontia minerals, and will tend to develop localities which heretofore have not been productive.

The amount of celestine mined in Sicily, the principal source of this mineral, is reported to have been about 4,000 gross tons in 1881.

DRIFT OR NOT DRIFT.—There are various opinions as to whether the mines that have been worked by hydraulic methods will hereafter be drifted. There is one question, the answer to which will surely determine the matter. That question is: "Will it pay?" Those mines the drifting of which will pay, will be drifted; such as will not pay to drift, will not be drifted. In the course of time all will be drifted, for in the course of time drifting all of them will pay. Any business that will pay will be followed; any business that will not pay cannot be followed for any great length of time. Mining is just like any other legitimate business, and it stands on no exceptional business principles. And because this is true is why we know that many mines around Grass Valley, that are now idle but have been worked in the past, will again be worked. The Allison Ranch, North Star and many other mines here will be again opened in time, and that because they will pay when worked in improved ways and with economical appliances. We have not a doubt but that mining will be successfully followed until the time the earth becomes as dead as the moon now is, which direful event will not happen for some millions of years yet to come.—*Foothill Tidings*.

USEFUL INFORMATION.

Queer Freak of Watches.

"Decidedly watches are queer things," said H. H. Hopkinson, of the *Jewelers' Circular*, seated in the easy chair of his editorial sanctuaries. "They possess some unaccountable peculiarities. For instance, some time about the beginning of last summer, when there had been a succession of fine displays of the aurora borealis, it was estimated that in a single night in the city of New York the main springs of not less than three thousand watches broke. This estimate is based on actual inquiries. Fine sensitive watches are particularly liable to be affected by electrical atmospheric disturbances. During the months of June, July and August, when these phenomena are most frequent, there are more mainsprings broken than during all the remaining months of the year. They break in a variety of ways, sometimes snapping into as many as twenty-seven pieces.

"It is a fact that since the introduction of the electric light has become so general a large number of watches, some of them very fine ones, have become magnetized. While in this condition they are useless as timekeepers. This defect should be considered incurable, and because of it thousands of watches have been thrown away after much money had been spent on them in vain attempts to persuade them to keep good time. Among the methods resorted to were washing the parts in garlic juice, refining and passing them through the fire. But all these devices were entire failures or only in part effective.

"I know of a man who had a fine and valuable movement which kept excellent time. He transferred it from a silver case to a second-hand gold one. Immediately it lost all of its characteristics of steadiness and reliability, and, in fact, did not keep time at all. When replaced in the silver case it kept good time again. The owner, a jeweler, puzzled himself, and experimented in vain to discover the cause of this strange partiality on the part of his watch for silver. At length he sent it to an expert. He discovered that the lifting-spring of the gold case had become magnetized. On substituting another for it, the watch kept as good time in the gold case as in the silver case.

"There are occasions when it is a very serious matter to have your watch magnetized. The most striking instance in point is one which lately came under my notice. Captain W. R. Smith commands the steamer *Delaware*, which plies between New York and New London. Before putting to sea, on a recent voyage, he was invited to inspect an electric light dynamo machine and examined its parts closely. Soon after getting on board the steamer he observed that the compass became strangely affected when he approached it. Whether he stood on the right or the left, or immediately in front of the compass, the needle would invariably point to him. The compass was worse than useless when he came near it. It was dangerous and might wreck the ship. You can imagine that this phenomenon alarmed and puzzled Captain Smith not a little. At length he recalled his visit to the dynamo machine and the true solution of the eccentric behavior of the needle flashed upon him. His watch had become magnetized. When he removed it the needle resumed its constancy to the polar star. On his return to the city he took the watch to a watchmaker, who demagnetized it for him. This firm has invented some machine, the mechanism of which is a secret, by which they demagnetize a magnetized watch speedily and effectually. They get watches sent them from all parts of the world to be thus treated.

"Watches frequently get magnetized in iron mines or in machine shops, where they are incautiously brought near swiftly running belts. I knew a workman who used to hang his watch between the parts of a running belt. He expended a small fortune on mainsprings.

"It is a well-known fact among horologists that no watch will keep the same time with two people. The cause has not yet been definitely ascertained, but it would seem that in some mysterious way a watch is affected by the temperament of the wearer. The mere physical differences in gait and movement between different people is not sufficient to account for all the variations that have been observed."

—*New York Tribune*.

THE "DUCONG," OR VEGETARIAN WHALE.—A writer in the *Gentleman's Magazine* gives some interesting particulars relative to this species of whale, now taken to a considerable extent in Queensland, and valuable alike for its oil and as food. Its size varies from eight to twenty feet in length; it lives upon submarine meadows of seaweed; it has no gills, but breathes air by means of lungs; its head is round and somewhat human like, and has hair something like that of a man's beard. It is said many stories of merman and mermaid may be traced to these creatures. Their oil is said to have all the medicinal merits of cod-liver oil without its unpleasant flavor; at ordinary temperature it deposits crystals, as olive oil does in frosty weather, but on warming slightly becomes liquid and clear. The flesh is much prized in Australia, being cut off in fitches and slabs, and it is stated that "from the same animal is taken meat resembling beef, veal and bacon."

A SUBSTITUTE FOR MATCHES.—Countless accidents, as every one knows, arise from the use

of matches. To obtain light without employing them, and so without the danger of setting things on fire, an ingenious contrivance is now used by the watchmen of Paris in all magazines where explosive or inflammable materials are kept. Any one may easily make trial of it. Take an oblong vial of the whitest and clearest glass, and put into it a piece of phosphorus about the size of a pea. Pour some olive oil heated to the boiling point upon the phosphorus; fill the vial about one-third full, and then cork it tightly. To use this novel light, remove the cork, allow the air to enter the vial, and then re-cork it. The empty space in the vial will become luminous and the light obtained will be equal to that of a lamp. When the light grows dim, its power can be increased by taking out the cork and allowing a fresh supply of air to enter the vial. In winter it is sometimes necessary to heat the vial between the hands in order to increase the fluidity of the oil. The apparatus thus prepared may be used for six months.

SHELLAC DISSOLVED IN BORAX.—It is well known that shellac dissolves in borax solution, and this solution is often utilized for various purposes, both as varnish and cement. The following are the proportions employed: Ten parts of borax, 30 parts of coarsely pulverized shellac and 200 of water. It is dissolved by warming on a steam bath for a few hours. When cold it may be filtered. To make it more pliable, add a few drops of glycerine. It may be given various colors by introducing soluble pigments: For black, it is recommended to use soluble nigrosine; red varnishes are obtained by adding eosine or fuchsine; for blue, either methylene blue, alkali blue or marine blue; for green, use malachite green or brilliant green; and for violet, methyl violet.

SHUTTING DOORS QUIETLY.—The application of a spring or suspended weight to shutting a door makes that shutting noisy. To remedy the evil two German mechanics have invented a pneumatic device, wherein the act of opening the door moves a piston away from a suction valve, causing air to be drawn freely through the latter. As the door is closed the piston returns, and the air has to escape, but can only do so by an aperture much finer than that through which it entered; hence, a brake-like action on the door.

A GOOD CEMENT.—Persons who use brass letters on glass windows or doors are often troubled by their dropping off, from unequal expansion or from too violent efforts on the part of the window cleaners. The following is said to be a sure cement. It should be mixed just before using: Litharge, two parts; white lead, one part; boiled linseed oil, three parts; gum copal, one part.

NOT A BAD COUNTRY FOR RAILWAYS.—The Mexican Central railway runs through twenty-one cities with an aggregate population of 896,609, and eight of them are State capitals. In these cities are seven mints, whose annual coinage is not less than \$35,000,000, and the agricultural valuation of the twelve States through which it passes is something like \$110,000,000.

GOOD HEALTH.

The Origin of Physicians.

The first physicians of whom mention is made in history were those who embalmed the Patriarch Jacob (Gen. chap. 50-2), by order of Joseph, his son. They are styled the servants of Joseph, whence it appears they were not priests, for the Egyptian priests had too much honor and influence with both king and people to be the servants of any man, however exalted his station.

The Egyptians attributed the invention of this art to Thoth, or Herms, who engraved its principles in hieroglyphics upon pillars. These hieroglyphical writings were supposed to have been transcribed into books by Agathodemon, or the second Mercury, which books the priests asserted had been preserved in the sacred recesses of their temples.

But the system of medicine among the Egyptians appears to have been nothing better than a collection of absurd superstitions. The ancient Greeks, likewise, according to the picture which Homer gives of them in the *Iliad*, seem to have possessed but a very low degree of this art. Esculapius was the first person among them who had any valuable knowledge of this kind; and his knowledge, probably scanty, procured him such respect that after his decease he was deified by his countrymen. Hippocrates, who claimed the honor of being the seventeenth in descent from Esculapius, was the first who treated of medicine in a regular and rational manner. Hippocrates is supposed to have lived about 400 years before Christ. He is the most ancient author whose writings on the medical art are preserved, and is therefore styled the father of medicine. He endeavored to explain the causes of the diseases of the human frame and their symptoms, to classify them, and to point out their preventives or remedies. He laid down maxims for the preservation of the health; for the regulation of exercise and bathing. He appears to have used purgatives, emetics, venesections, sudorifics, moist and dry fomentations, gargles for the throat, oils and ointments, cata-

plasm, mixtures composed of various substances to soften tumors and disperse swellings, and various other compounded medicines. Celsus was another celebrated ancient writer on the subject of medicine. He lived in the time of the Roman Emperor Tiberius. In the reign of Adrian, A. D. 131, lived Galen, a native of Pergamus, one of the most illustrious men in the annals of medical science. After the downfall of the Roman Empire, the Arabian or Saracenic physicians became illustrious for the knowledge and practice of the art of medicine. To them Europe is indebted for the preservation of the medical science of Greece and Rome, and likewise for the description of many new diseases, and the mode of treating them. Of these Avicenna was the most famous. Their system of medicine was introduced into Europe very early with great success.

In the beginning of the sixteenth century, Paracelsus, a famous chemist, advanced a new system of medicine, founded on chemistry. In 1628, the celebrated Harvey demonstrated and communicated to the public the important discovery of the circulation of the blood. This overthrew almost all the former systems, and prepared the way for that highly improved state in which the medical art exists at present.—*Sanitary News*.

CHARCOAL AS A FOOD.—Whatever increases the power of laying on fat, or promoting the rapid and healthy production of flesh, must be food or equivalent thereto. This pure charcoal does most effectively, as recently proved by taking the live weights of two lots of sheep, and simply separating them by an ordinary net, the artificial food, corn and cake, being carefully weighed out to each lot alike daily, one pint of charcoal being added to one lot only. When re-weighed prior to selling to the butcher, the increase in weight was in favor of charcoal by 16 1/2 per cent. Sanitation causes easy and complete digestion, and assimilation only can account for these results, which charcoal alone can accomplish. The charcoal should be given mixed with the food, except in urgent cases, when it may be mixed in water or thin gruel, and given as a drench. The dose is one pint to every twenty-five head of sheep or lambs. One-quarter pint per head for full-grown cattle, horses or pigs; half the quantity for young cattle, and two teaspoonfuls to one dessert-spoonful for young calves, daily, when suffering from disease, or in ill condition. To keep in good health and fortify against diseases, the dose should be given two or three times per week according to the class of food they are having, and the state of the atmosphere. The best plan is to wet a quantity of bran, pollard, or malt combs, mix the charcoal amongst it, and then amongst the food you give them. For rapid and healthy fattening of cattle it should be used daily amongst their food. Charcoal for internal and medicinal purposes must be pure vegetable charcoal, free from all irritating and injurious foreign matter. The charcoal, when coming into the user's possession, must be kept perfectly dry and free from any ill-smelling surroundings, such as the vapors of a stable or artificial manures, etc., or it will absorb them and thus become septic, and of no medicinal value. It is better kept in a closed bin or tin canister with a closely fitting cover.—*Farm and Home*.

WHAT TO DRINK TO KEEP YOU WARM.—"If you want a drink that will keep you warm a whole night long out of doors," said an old policeman to a friend, "don't drink whisky or rum, or any liquor. The heat they afford is short lived, and leaves you cold and weak. They are worse than nothing; but drink a glass of ale and pepper—new ale and common black pepper. It will not affect your head, but it will keep your blood warm in the keenest wind and coldest rain." "I never tried the pepper part of that prescription," said a Third Avenue car driver, "but ale is, I know, thought to be very warming. We car drivers have colder work than policemen do, I think, and the old ones among us have tried every drink you ever heard of. A lot of us were talking the whole thing over the other night. Hot rum, hot whisky, brandy and ginger, and all the cold clear alcoholic drinks were discussed. But the majority were in favor of hot coffee. That is the least hurtful, the most heating, and the longest lasting drink I know of."—*New York Sun*.

TO CURE DRUNKENNESS.—A medicine for drunkenness is red Peruvian bark (*cinchona rubra*). A pound of it is powdered and soaked in diluted alcohol. It is then evaporated down to half a pint. The imbriate is given a teaspoonful of the medicine every three hours, and his tongue occasionally moistened between the doses during the first and second days. The third day the dose is generally reduced to half a spoonful, then to a quarter of a spoonful, and gradually lessened to fifteen, ten and five drops. This treatment is continued from five to fifteen days, and in bad cases to thirty days; the average is about seven days. The result is said to be a lasting dislike for liquor in any form.

The essential elements of healthy recreation, according to Sir James Paget, are "uncertainty, wonder, and the exercise of skill." It would be worth while to see how many of these elements enter into the conventional "Sunday excursions," so much praised by the popular press for their health-giving qualities.

TABLE OF CONTENTS.

EDITORIALS.—Pacific Coast Clays; Young Men's
Scientific Society; Long Hole Drilling; Indian Signal-
ing, 85. Passing Events; California Mineral Re-
sources; Safety Devices; Increase of Cost with Depth;
Freakish Gas Meters; San Diego Coal, 92. The Cen-
tral-Alene Placers; Final Decree of the Debris Suit;
Aluminum in Nevada, 93.

ILLUSTRATIONS.—Indian Signal of Discovery or
Alarm, 85. Northern Pacific Railroad Map Showing
Location of the Cenr d'Alene Mining Region, Idaho,
98.

CORRESPONDENCE.—Montana Mines; Elko
Mines, Nevada, 86.

MECHANICAL PROGRESS.—Method in the
Workshop; Interesting to Workers in Metals; Lathe
Pulley Faces; Painting Iron; A Mechanical Test of
Coke; A New Rotary Engine; Effects of Heat on Saw
Teeth, 87.

SCIENTIFIC PROGRESS.—The Uniformity of
Nature's Laws; The Gospels of Work and Rest; An Im-
proved Phonograph; Telephoning over the Sea; The
Nature of Electricity; Lower California; Found in the
Great Deep; A Dry Galvanic Battery, 87.

MINING SUMMARY.—From the various counties
of California, Nevada, Arizona, Idaho, Montana, New
Mexico, Oregon and Utah, 88-89.

USEFUL INFORMATION.—Queer Freak of
Watches; The "Digons"; or Vegetarian Whore; A Sub-
stitute for Matches; Shellac Dissolved in Borax; Shut-
ting Doors Quickly; A Good Cement; Not a Bad Coun-
try for Railways, 91.

GOOD HEALTH.—The Origin of Physicians; Char-
coal as a Food; What to Drink to Keep you Warm; To
Cure Drunkenness, 91.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board, Notices of Meetings, Assess-
ments, Dividends and Bullion Shipments, 96.

MISCELLANEOUS.—Gold Quartz for Jewelry, 89.

Passing Events.

During the past week California has experi-
enced one of the most welcome rains possible.
The water has fallen in abundance and fallen
all over the State. The agricultural popula-
tion are hard at work, and the miners—all ex-
cept the hydraulic—rejoice too. The gravel
miners, however, are compelled to see the water
pass by without being used. The rain has re-
vived business, for the State may now look for-
ward to a prosperous year, though only a week
or so ago there was a prevailing feeling of
depression.

The principal topic of conversation among
miners just now is the expected "rush" to the
Idaho placers. Every item or news from the
Cenr d'Alene region is read with avidity. So
far there seems to be a very general belief in the
richness of the mines, though the region itself
is not by any means attractive. Men are start-
ing every day for the mines, notwithstanding the
great expense entailed and the hardships of
travel. Moreover, little can be done there at
present. The snow is four or five feet deep
the weather very cold, and no chance for any
work to be done.

The developments made in some of the
Tombstone mines during the last two weeks
are encouraging in the extreme. Ore bodies
have been discovered in several of the mines
that have been lying idle for months, and in
several cases these ore bodies promise to be
rich and extensive. Development work is be-
ing vigorously prosecuted in all directions with
the most favorable results.

California's Mineral Resources.

Many people imagine that California's posi-
tion as a mining region depends entirely on her
gold product, for which she has been famous
since mining was commenced here. There are
many other minerals, properly designated as
economic minerals, which exist in California in
more or less abundance. Coal, iron, salt and
clay are the foundations of many manufactures.
The last three mentioned are found here in
abundance, and coal suitable for most purposes
is also found here.

If the economic minerals found in California
cannot be made immediately available it does
follow that they are less valuable. It is too
often the case that those finding deposits of min-
erals regard them only as a source of immediate
profit; and if they cannot be made available at
the moment are considered comparatively
worthless. A list of the most important econ-
omical minerals has been made out by State
Mineralogist Hanks, and we give here those
that have been found in this State.

Of building materials there are the following:
Alabaster, asphaltum, agalmatolite (or figure
stone), broken stone (for rubble, pavements,
etc.), basalt, bitumen, cement stone, diorite,
fire-stone, diatomaceous earth, feldspar, gneiss,
greenstone, gypsum, hydraulic limestone, indur-
ated volcanic ash, lava, limestones, marbles,
sand, sandstone, schist, serpentine and slate.

Of clays there are blue clay, brick clay, fire
clay, Kaolin (or porcelain) clay and terra-cotta
clay.

Of fuels there are bituminous shale, coal, lig-
nite, peat and petroleum.

Of mineral manures we have coal slack (or
dust), gypsum, nitrate of soda and other.

Of gems and semi-precious stones there are
the following: Bloodstone, cat's-eye, chalcedony
diamond, jasper, j-t, malachite, onyx and
opals.

Then there are found in California ores and
minerals containing antimony, arsenic, bismuth,
cobalt, copper, chromium, iodine, iron, iri-
dium, lead, lithium, manganese, mercury,
molybdenum, nickel, palladium, platinum, soda,
tellurium, tin, tungsten, vanadium and zinc.

Among other economic mineral productions
of the State are alum, asbestos, boracic acid,
horax, hurr millstone, chromic iron, feldspar,
glauberite, graphite, Iceland spar, lithographic
stone, pumice stone, pyrites, quartz, red chalk,
salt, sulphur and therandite. Most of our atten-
tion has, of course, been paid to gold mining.
But we produce considerable coal, iron, quick-
silver, chrome, copper—in fact, a number of
mineral substances in abundance—and these econ-
omic minerals are good, permanent sources of
wealth. As the country is more densely popu-
lated many branches of mining not now profit-
able will become so.

Safety Devices.

Here among us the compartment shaft system
has long been recognized as the best, the single
shaft, or rather single compartment shaft, being
confined to shallow mines. On the continent
in the big coal mines the custom of reserving
one shaft exclusively to the use of drawing
coals is gaining favor. In such a case a second
shaft, called the *puits de service*, is set apart for
the men and for lowering materials into the
mine. Where possible a third shaft is used as an
upcast for the ventilation. With an arrange-
ment of this nature, the drawing cages may be
constructed suitably to the one kind of work
required of them, and it is, therefore, the prac-
tice to design them differently in some respects
to gain comfort and safety. The cage of the
puits de service is alone provided with safety
catches, when these are used at all. Mr. Andre,
the mining engineer, reports having observed
one of these devices not long ago, which was
constructed to grip a wire rope fixed for the
purpose instead of the guides. The wire was
secured at the bottom of the shaft to a balk of
timber, and at surface was passed over pulleys
and connected with a series of weights resting
upon a platform. In the case of the cage break-
ing away, a set of cams attached to it grip the
wire rope, and, as the cage descends, the
weights are lifted one after another. The
object of this arrangement is to bring the cage
to rest gradually, and so to avoid the sudden
and dangerous shock which results from the
catches gripping a fixed support. Some trials
lately made to test the efficiency of these safety
devices showed there action to be very satis-
factory. The practice, common on the conti-
nent, of lowering into the mine the materials
required for packing, occasions a great deal of
work in the *puits de service* in the intervals
between the raising or lowering of the men.
From the quarry whence the materials are
obtained to the shaft, the transport of the tubs
is effected by mechanical haulage, usually by
the method of the endless rope.

Increase of Cost with Depth.

The cost of drilling deep holes with the dia-
mond drill in rocks of moderate hardness is cer-
tainly much greater than by the rope drilling
process, as practiced in the Pennsylvania oil
regions, and the progress made is also much
slower. The cores obtained may or may not be
worth the differences in time and money. When
a large number of comparatively shallow
holes are to be drilled in hard rocks, or pros-
pecting holes are needed from some point in-
side a mine, or where inclined or horizontal holes
are required, the diamond drill gives the best
results. When a large number of holes of mod-
erate depth are drilled by a corporation owning
and operating the drill the cost per foot may,
by proper arrangement, be much reduced.

Mr. Lewis A. Riley, in Vol. V, page 306, of the
Transactions of the American Institute of Min-
ing Engineers, reports the average cost of 24
bore holes (ranging from 100 to 900 feet in
pepth), aggregating 9,902 feet, at \$2.22 per
foot. Their average depth was about 400 feet.
The average progress made in 10 hours was 18.9
feet. This estimate of \$2.22 cents per foot
covers everything except royalty, interest or in-
vestment, and wear and tear, for which 20 or
30 cents should be added.

For holes double this average depth the
cost per foot would probably be nearly, if not
quite, doubled. Mr. Riley divides the cost thus:

Labor.....	\$1.15
Diamonds.....	.66
Fuel, Water and Repairs.....	.41
	\$2.22

The figures given by Mr. O. J. Heinrich in
volume 2, page 241 of the transactions of the
American Institute of Mining Engineers, show
how rapidly the work of drilling by this
method measures with the depth. The boring
was done at the Mithothian collieries in
Virginia.

Depth of Hole.	Cost per foot including Interest.
419 feet.....	\$1.86
850 feet 3 inches.....	2.43
1142 feet.....	3.62

The estimates were based on the following
scale of wages for a twelve-hour shift:

Skilled Labor (foreman, etc.).....	\$2.50 per day
Engineers.....	2.00 "
Assistants.....	\$1.50 to 2.00 "
Laborers.....	1.00 "

The cost of the drilling for labor per foot
was:

For 419-foot hole.....	\$.35
For 850-foot hole.....	.59
For 1,142-foot hole.....	1.02

These comparisons illustrate that the basis of
cost of the first 50 or 100 feet cannot, by any
means, be relied on as the correct basis for the
work as the holes deepen.

Freakish Gas Meters.

Everyone who keeps house and burns gas
knows what queer things gas meters are. There
are times when they seem to be endowed with
supernatural vitality that enables them to go on
registering when the house is shut up and no
gas is burned. It is most likely the force
of habit, but the companies of course are not to
blame for such vagaries. When their meters
report a certain amount of gas material con-
sumed, what else can they do than to make out
their bills and insist on payment. It is the
guilty gas meter that is to blame; and yet,
strange to say, it is difficult to bring the people
to a realization of this fact. Last summer Gen-
eral Siciles closed up his house in New York
and went to Europe, but before he left he took
the precaution to cut off the gas supply near
the meter. But that self-willed whimsical in-
stitution went right on registering all the same,
and of course when he came home a bill was
presented which, he promptly refused to pay,
and also prevented the company from shutting
off his supply by suing out a writ of injunction.
After considerable litigation, it has recently
been decided by the courts that a company must
prove the justice of its claim before it can col-
lect a bill. Perhaps the sympathy of every
community will be with the company and
against General Siciles for disputing the an-
cient integrity of gas meters. The fact that he
had closed his house and gone to Europe cuts
no figure in the case; and then, if a respectable
gas meter should take a notion to lie, how are
the companies to find it out? It may keep on re-
porting the month's figures over and over again,
but who is to blame? If people will burn gas and
have meters in their houses they must put up
with such vagaries. Such freakishness is very
common, and likely to happen in the best of
families until the custom of using electric lights
is thoroughly established, and then perhaps
these meters will be cured of their fantasies.

A LETTER received at Silver City, Idaho, from
a gentleman in Cenr d'Alene, says that mining
region is as rich as Boise Basin ever was, and
by far more extensive. Much gold-bearing
quartz is found. Nothing can be done there
before June.

San Diego Coal.

Some new coal fields have recently been dis-
covered in San Diego county, in this State. The
coal mine is called the McIntosh and Cheney
mine. It lies in a southerly direction from
Colton some twenty-five miles, and from Laguna
Station, on the California Southern, four and a
half miles. The land lying between the mine
and Laguna Station is a level plain. By means
of a side track there could be some fifty villages,
towns, etc., in a radius of fifty-five miles,
supplied with home coal, including Riverside,
Colton, San Bernardino, National City, Los
Angeles, etc. These places are now compelled
to pay high prices for coal. The new find, if it
turns out as is hoped and expected by its
owners, will be of great benefit to Southern
California. At present the coal used there is
shipped from Coos Bay, Bellingham Bay and
the Rocky Mountain coal fields.

From a gentleman who lately visited these
mines, we obtain the following information:
The property consists of 640 acres. The dis-
coverers and owners claim 400 acres of coal.
The developments are as follows: On the east
side of the mountain a tunnel was started on
blossom of coal. At forty feet in, the deposit
was struck. At this point the thickness was
4½ feet. From this point the tunnel has been
pushed vigorously through the coal for 240½
feet, disclosing 200½ feet of coal. At the end of
tunnel the thickness of the coal is 7 feet 3 inches
solid. With the limited means the discoverers
have had they have done wonders. As the
tunnel penetrated through the coal, I am in-
formed by the owners, samples have been sent
by Mr. McIntosh & Cheney to San Francisco
for analysis. The tests have been made by H.
G. Hanks, manager of the State Mining Bureau,
and W. D. Johnson, mineralogist and assayer; the
different analyses varying in fixed carbon from
35.35 to 46.82; Volatile matter, 30.40 to 40.27;
water, 10 to 23; ash, 5.36 to 11.25. The vein
of coal shows a remarkable uniformity in thick-
ness, pitch and direction throughout its devel-
oped length.

The coal is nearly identical in character here
with that being received by consumers from
Mount Diablo, Coos Bay. Over 150 tons of
coal have been sold at the mouth of tunnel since
August, 1883, purchased by hotels, canneries,
private residences at Colton alone. The coal is
put in bags in the tunnel by Mr. Cheney, and
wheeled to the mouth of tunnel and sold as per
order from teamsters. The owners claim one
man extracts daily five tons. No powder up to
date has been used in the mine.

In this old way of mining the coal has cost
to mine and deliver at mouth of tunnel \$1.50
per ton. With modern improvements, car-
track and improved cars, this coal can be mined
and delivered at the mouth of tunnel for 50
cents per ton. The late discovery of rich gold
ledges in Pinacate mining district, only 2½
miles from this coal mine, is important. All
mines have a history, and it is only brought to
the public ear through some enterprising paper.
All these new discoveries are worth millions to
the State of California, and every new develop-
ment should be encouraged. Discovered in a
part of California noted only for grapes, oranges,
and tropical fruits, and barren of wood and for-
ests, it is surely one of the grandest discover-
ies that have been made for years in San Diego
and San Bernardino counties. But coal mining
is a new business in Southern California, and
experience and capital are wanting. Still, be-
fore long, no doubt, the mine will be properly
opened.

Saving Gold.

EDITORS PRESS:—In reading over your valu-
able paper of the 19th ult. I see one of your nu-
merous correspondents suggests that the min-
ing public should meet and discuss on some bet-
ter method for the recovery of gold. I do not
agree with your correspondent that the loss is
as much as he says, nor do I want to enter into
any discussion with the Doctor further than
what concerns myself. He says: "I am, from
what little I know of Morris' system, inclined
to think well of his process, but he must demon-
strate, by actual working tests of large quan-
tities, that his method is what he claims it to
be." What would be better to demonstrate my
desire to try my process than to say that only
a little over two months ago I offered to pay a
gentleman very well known to Mr. Drake for
the tailings running off. He answered me that
he saved all the gold. I went again, at his re-
quest, to his house, where I again asked to buy
his waste, when he told me "Mr. Morris, stop
right here, and do not mention about the tail-
ings any more, as you can't get them, not even
if you put right down here on the table \$1,000
for every ton of ore we crush." Of course, that
ended the matter. I then went to an acquaint-
ance in Sonora that I thought had some in-
fluence with the gentleman referred to, for him
to see if he could not get the tailings for me on
some terms. That gentleman referred me to
the owner in San Francisco, and where I had no
better result. I made a very liberal offer, and
I am ready at any time any one is willing to
give me the opportunity to fully demonstrate to
Mr. Drake or any one the value of my process.

FRED MORRIS.

San Francisco, Jan. 28, 1884.

The Cœur d'Alene Placers.

The Cœur d'Alene placers are way up in the northern corner of Idaho, where the width of that Territory is circumscribed by Montana and Washington, apparently having more than their share of the land. The nearest railroad town is Rathdrum. The map we give herewith shows the Cœur d'Alene region, and its relation to the railroad, and also the position of Rathdrum. People are still going into the region though the snow is deep.

People are coming in via Trout creek, which is the nearest point on the Northern Pacific railroad, distant about seventy-five miles. They come in from one to two days on snowshoes. A letter from Spokane to the *Truckee Republican*, written by P. J. Ward, says: There is considerable excitement in this city about the Cœur d'Alene mines. Some few from here have already started with their outfits for the mines. Two dog trains left here for the diggings yesterday, with almost 150 pounds of freight to the dog. They expect to get there in five or six days. The Cœur d'Alene mines are about 100 miles from here. From Spokane to the Mission, about 60 miles, the trail is good, but the rest of the trip is hard and dangerous. There is some talk of opening a road from Spokane to Eagle City, which is the principal town in the Cœur d'Alene mountains. In case the road is opened, Spokane, it is thought, will be the miners' headquarters. The weather is so cold that the road may not be opened for some time yet. There are three or four different routes to the mines. Rathdrum route is the one most traveled. Rathdrum is about

Final Decree on the Debris Suit.

Deputy U. S. Marshals are serving the final decree in the debris suit on the hydraulic miners in parts of this State. Marshal Peterson has been in Nevada counties serving notices, among others, on the Superintendent of the Milton, North Bloomfield, Sailor Flat, Mazanita, Omega and Excelsior claims. There has been no attempt on the part of the miners to evade the service, and the Marshals have been treated with courtesy.

The following is the final decree in the case of Woodruff vs. the North Bloomfield Mining Co., which case was decided early in January, by Judge Sawyer, and this final decree filed January 23, 1884:

This cause came on to be heard upon the bill, answer, depositions and the other proceedings in the case, and was argued by counsel.

On consideration whereof, it is by the Court ordered, adjudged and decreed as follows, to-wit:

That as to defendant, the Conly and Gowell Consolidated Mining Company, the bill be, and it is hereby dismissed.

And that the defendants herein, to-wit: the "North Bloomfield Gravel Mining Company," and its officers, agents, servants and employees, and each and all of them, and the "Milton Water and Mining Company," and its officers, agents, servants and employees, and each and all of them, and the "Omega Gold Mining and Ditch Company," and its officers, agents, servants and employees, and each and all of them, and the "Excelsior Water and Mining Company," and its officers, agents, servants and

defendants or defendant so applying, upon any showing which the Court may deem sufficient that the conditions have been so changed that the discharge of such mining debris by said parties or party, so applying, into said streams, or any of them, may be resumed or otherwise conducted, so as not to create, or continue, or contribute to create or continue the nuisance complained of, or a nuisance of a similar character, and so as not to injure or damage, or contribute to injure or damage said complainant, or upon any other grounds hereafter arising satisfactory to the Court. And for the purpose aforesaid, the Court hereby reserves the power to modify or suspend said injunction in whole or in part, as the exigencies and equities of the case hereafter arising, may require.

(Signed), LORENZO SAWYER,
Circuit Judge.

Aluminum in Nevada.

[By our traveling correspondent, B. W. CROWELL.]

The Stock Exchange mine is situated about 200 yards west of the Navajo mine. The ledge is about 8 feet thick and traceable for a long distance without excavating. As yet it is only prospected to the depth of 45 feet, and so far, the assays in gold and silver are low grade sulphide ore. No drifting has been done. There is some water already in the shaft.

Passing through the ledge proper, the gold and silver bearing vein, they encounter a large body of aluminum ore—a very fine quality of porcelain clay, containing 85 per cent silicate of alumina, as reported by an analyst.

Mr. E. M. Laferty, the locator, has a certificate of assay made by Prof. Price, of San Francisco, giving in 100 parts of the ore assayed by

gives many valuable alloys, as with copper, giving aluminum gold; with silver, bismuth, etc., giving non-corrosive bronzes; some of which are especially valued for mine fittings and appliances, or for any machinery exposed to corrosive agents.

These bronzes are susceptible of being rolled down to nice gauge work and make elegant cups, vases, covers, knives, forks and almost all kinds of household metallic wares. In many respects it is superior to silver in its resistance to the action of various chemicals. It has been much used in the manufacture of very delicate balances, and assay scales. Some of its special features are best understood when given in comparison with some of our common metals:

METAL.	One cubic foot weighs—	Tensile strength in lbs. per sq. inch.	Length of bar cast in one foot length, its own weight only.
Aluminum.....	168	20,880	23,000
Steel.....	490	75,000	23,000
Wrought iron.....	480	50,000	15,000
Brass.....	5	30,000	9,800
Cast iron.....	443	10,500	5,950

The most valuable experiments and successful practical results pertaining to the extraction of this metal have been attained in France, and from the Paris Aluminum Society the principal supply of this metal is obtained. The Webster processes and experiments have been kept carefully as secrets, but parties claiming to be informed explain it in these words: "A given quantity of alum and pitch, which are first finely pulverized and mixed together in a calcining furnace, by which means 38 per cent of water is driven out, leaving the sulphur, potash and

NORTHERN PACIFIC RAILROAD MAP, SHOWING LOCATION OF THE CŒUR D'ALENE MINING REGION, IDAHO.

30 miles east of Spokane. Trout creek route is over 100 miles from here. I intend to go to the mines about the first of February. There are about 300 men there now, but they can do nothing, the snow being about four feet deep on the level, yet there are men going out and in every day. Flour is worth \$50 a barrel, there.

Samuel Allison, on Tuesday of last week, passed through Deer Lodge, Montana, en route to Butte, from the Cœur d'Alene mines. He reports to the *New Northwest* a good passable trail open from Trout Creek station, on the Northern Pacific railroad, to Eagle City, a distance of about 35 miles. He walked over the trail between the above two points in 18 hours, and said that aside from one high summit to cross, the traveling was as good as along the streets of Deer Lodge. Mr. Allison has a claim in the new El Dorado, and feels sanguine that it will pan out well when he gets prepared to work it properly. His claim, in common with others, embraces 20 acres, but as a rule locators of these large tracts have taken in from three to a dozen partners, thus dividing the ground up among a large number of people. Being questioned as to the proposition made by the miners to cut claims down to small lots, he said that any arbitrary action on the part of the miners looking to that point would be after all laws of the county and Territory had been exhausted, resisted by the Federal government. At least a communication from the Secretary of War at Washington had been received to that effect. Between 600 and 1,000 men are now in the diggings, but little was being done other than building houses and preparing spring. The first of next June has been fixed upon as representation day; and, according to resolutions passed at a recent miners' meeting, further jumping of claims will be prohibited until that date. The miners now feel secure in their rights, and are not afraid to leave the camp in search of means and provisions with which to work their claims.

employees, and each and all of them, and also B. D. Chadwick, sued herein by the name of D. B. Chadwick and O. D. Campbell and the firm or partnership of Chadwick & Campbell, composed of said two last named persons, and their each and all of their agents, servants and employees, and Hannah Conly, as executrix of the last will and testament of John Conly, deceased, and who is substituted as a defendant in place of said decedent, and Orrin Gowell, and their each and all of their servants, agents and employees, are perpetually enjoined and restrained from discharging or dumping into the Yuba river, or into any of its forks or branches, or into any stream tributary to said river or any of its forks or branches, and especially into Deer creek, Sucker Flat ravine, Humbug creek, Scotchman's creek, any of the tailings, boulders, cobble stones, gravel, sand, clay, debris or refuse matter from any of the tracts of mineral land or mines described in the complaint. And as from causing or suffering to flow into said rivers, creeks or tributary streams aforesaid therefrom, any of the tailings, boulders, cobble stones, gravel, sand, clay or refuse matter resulting or arising from mining thereon. And also, from allowing others to use the water supply of said several mines or mining claims, or any part thereof, for the purpose of washing into said rivers and streams, any earth, rocks, boulders, clay, sand or solid material contained in any placer or gravel ground or mine.

2. That the complainant recover of the defendants above named, save the Conly & Gowell Consolidated Mining Company, his costs in this suit, and the same be paid by said defendants to complainant.

3. That the defendants, or either of them, may, at any time hereafter, apply to this Court upon due notice to the complainant or George Caldwell, Esq., his solicitor, for a modification or suspension of this injunction as to such

him 19.48 parts of metallic alumina, or nearly 20 per cent of metal, 389.6 pounds per ton of ore which is generally quoted at about \$2 per pound, or \$779.20 value.

These figures look large for value to exist in a fine, pure clay. If they are reliable, then the question most prominent is in regard to the quantity of this silicate and its accessibility.

This mine of alumina forms the foot wall of the Exchange silver mine, and is of great thickness, as the bottom of it has not yet been reached nor any limiting boundaries, except the ledge above. My attention was first called to it by seeing a painter using it as a white paint for his dwelling, and noticing the pure white covering of the wood. It mixes readily with hot water, and forms a very smooth, soft white paint—differing very much from lime by retaining its consistency more as past; instead of settling—and thus admits of giving the surface a perfect covering at one brushing.

From what I saw of it when used as a white-wash, I would infer that when properly ground with oil it might be found a cheap substitute for white lead, and in pure whiteness fully equal to it; and possibly retain its pure whiteness longer than the other, as aluminum is a metal less easily tarnished by exposure than silver. As a paint alone this may yet enrich its owners, as the salt, soda and borax beds, that for years were unvalued are now producing large revenues to their owners. So may these great resources for a very valuable metal soon attract the parties who may have the knowledge and the financial ability to utilize this rich deposit. Some claiming practical knowledge, say this will with the proper additions, produce the finest of porcelain ware. If the residue after taking out the metal can be used either as paint or for porcelain, it is in that case enhanced much in its value.

It is a very valuable metal where lightness or non-corrosive properties are essential. It

alumina with oxide of iron. The calcined mixture is then put into vertical retorts, and steam and air are forced through, which leaves a residue of potash and alumina only. This residue is afterwards placed in a vat filled with warm water, which is heated with steam. Potash is thus leached out and alumina left as a deposit. The potash liquor is then run off, boiled down, while the alumina precipitate is collected in sacks and dried. It is then ready for making chloride of aluminum.

Alumina deposit thus obtained contains about 84 per cent of pure alumina, while that which is obtained by the old process of precipitation has only 65 per cent.

The constituents of Mr. Webster's alumina deposit, as analyzed by Professor Jones, are given: Alumina, 84.10; sulphate zinc, 2.63; silica, 7.40; water, 4.20; alkaline salts, 1.62. In order to complete the process and convert it into aluminum (the metal), the chloride of aluminum is treated with sodium in order to withdraw the metal.

If this bed of rich aluminum clay will verify these representations as to quantity and assay value in metallic per centage, it will yet command the attention of foreign scientists and men of capital, if the State of Nevada, with its School of Mines, cannot give it proper attention. Let France take a back seat in the production of this very useful metal.

NEW MINES.—Frank Raymond and James Hambley, who have been prospecting in Bottle Creek mountains, some forty miles northwest from Winnemucca, have discovered new mines. They find well defined leads carrying plenty of ore of a low grade. They assay from \$20 to \$40 per ton.—*Silver State*.

THE *Pioche Record* warns people hunting work not to crowd to Bristol, as that place is already overdone.

CHICAGO

FRAZER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved Burn. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. R. Haggin or Grant and Old Abe Co., Black also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36, of every form, made of Fine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

WHITNEY & MARSHALL,

22 and 24 Fremont St.,
SAN FRANCISCO. - - CALIFORNIA.

Sole Agents for the

Gordon & Maxwell Steam Pumps
and Pumping Machinery.

THE NILES' TOOL WORKS.

E. GOULD & EBERHARDT,

Manufacturers of
IRONWORKING MACHINERY.

working

GOLD, SILVER and LEAD
IN THEIR VARIOUS FORMS.

PRENTISS SELBY, - - Superintendent

San Francisco Cordage Factory.

Established 1853.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.

TUBBS & CO.,
611 and 613 Front St., San Francisco,

F. A. HUNTINGTON,

No. 45 Fremont Street, San Francisco, Cal.

CENTRIFUGAL ROLLER QUARTZ MILL!

After running one of these mills on the Whidden mine, in El Dorado County, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop-stamp mill:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it, and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

SHINGLE MACHINES AND SAWMILL MACHINERY OF EVERY DESCRIPTION.

[ESTABLISHED 1864.]

THE MOREY & SPERRY MINING MACHINERY COMPANY,

Successors to MOREY & SPERRY,
—Manufacturers of all kinds of—

Mine and Mill Machinery

WAREHOUSES: 92 & 94 Liberty St., New York. Newburg, - New York.

The Foundry and Machine Shop has been enlarged, we are now prepared to make from the most improved patterns QUARTZ and STAMP MILLS complete, for working GOLD and SILVER ORES.

MOREY'S IMPROVED PULVERIZER.

Steel SHOES and DIES for Stamps, and Mine and Mill Supplies. Agents for IMLAY ORE CONCENTRATOR and the MINERS' HAND ROCK DRILL. Information and Estimates cheerfully given. Send for Catalogue.

Address, THE MOREY & SPERRY MINING MACHINERY CO.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

WATER WHEEL.—Robert Hewson, S. F., Assignor to Globe Manufacturing Co., S. F., No. 292,431. Dated Jan. 22, 1884. This invention relates to certain improvements in water wheels or motors, and it consists of peculiarly formed buckets and a case having a diaphragm with inclined discharge holes so placed with reference to the wheel that the first impulse will be given by the motion of the water striking the front portion of the bucket, while the water escaping through the rear portion of the buckets gives a re-actionary force; and also in a manner for regulating and controlling the flow of water through the wheel. The wheel is designed for light work, such as driving sewing or other small machines, and the inlet pipe is intended to be screwed directly upon a common cock or faucet, the shaft thus lying horizontally and the belt from the pulley may lead directly to the machine.

SHEEP ENUMERATOR.—Henry A. Shipp, Fresno City, Fresno county, No. 292,373. Dated Jan. 22, 1884. This is a peculiar device for automatically counting sheep or other animals. The object is to facilitate the counting of animals which herd together in large numbers, and to insure the accuracy of the count; also in selling a number of sheep a discussion may arise as to the accuracy of the count, and this necessitates a re-count which, in the ordinary method, causes delay and is scarcely more to be relied on than the first count. The animals, as they pass through a gate from a corral, strike jamb flaps, on a "dodge-gate," by which recording mechanism is operated to record the passage of the animals passing through.

COOKING STOVE.—Robt. S. Burns, S. F., No. 290,316. Dated Dec. 18, 1883. This improvement consists in a double construction, with one shell within the other to provide a space between the two to receive the heat from the inner or fire chamber and conduct it to the ovens, and in certain return passages for the smoke and unconsumed gases, whereby they are subjected to a continued high temperature for more perfect combustion, together with secondary air supply passages and an arrangement of ovens.

EDGER.—J. A. Robb, S. F., No. 290,358. Dated Dec. 18, 1883. This invention relates to certain improvements in that class of machines for resawing lumber into scuffling, studding, etc., now known as "edgers." It consists of a means for raising and lowering the upper feed rolls and for controlling the mechanism by which this is done, and also of a means by which the feed rolls are connected so as to be driven simultaneously, notwithstanding the various distances to which they may be separated.

CARTIDGE-LOADING MACHINE.—Jonathan B. Richardson, Mountain View, Santa Clara Co., No. 288,740. Dated Nov. 20, 1883. This invention relates to a new and useful cartridge loading machine, and it consists in the means for receiving and supporting the shell, and in the means for charging it with powder, wads and shot. The object of the invention is to provide a simple and effective machine for loading cartridges.

DIRT SCRAPER.—Daniel A. Faulkner, No. 290,410. Dated Dec. 18, 1883. The invention relates to a new and useful dirt scraper for leveling land, and it consists in a peculiarly mounted and suspended bowl, and a novel means for dumping it. The mechanism is simple, rendering the device an efficient implement for leveling or scraping land.

WINDOW BLIND.—Joseph Williams, San Jose, No. 291,254. Dated Jan. 1, 1884. The invention consists of a series of slats united by a flexible connection and sliding upon rods or guides

upon which they are mounted, in such manner as to enable them to slide back and forth on said guides, and to turn from one position to a position at right angles to open or close the window. The object is to provide an easy-working and economical window blind.

VAPOUR LAMP BURNER.—J. C. Ludwig & Wm. Wainwright, S. F., No. 290,337. Dated Dec. 18, 1883. This invention relates to that class of lamp burners which are adapted to volatilize liquid hydro-carbon, and commonly known as vapor burners; and it consists in a novel construction of parts and arrangement of jets or holes to produce a fan-shape similar to a gas burner.

The Use of Belting.

A second edition of the standard work on "The Use of Belting," by Jno. H. Cooper, has been issued, and is for sale here at Bancroft's. The book contains numerous illustrations of approved and actual methods of arranging main driving, quarter-turns, and various belt fastenings; rules and various principles for speed or calculating the size of driving power of belts; plain, particular and practical directions for the treatment, care or management of belts, description of many varieties of belting, and chapters on the transmission of power by ropes, iron or wood, frictional gearing, and the strength of the belt leather, the experiments of Morin, Briggs and others for determining the friction of belts under different tensions. The collection of rules, statistics, etc., with reference to all the points connected with belting or belting, is most complete and full. No better assimilation of belt data can be made than that presented in this work. The facts and figures given were first compiled for private use, then printed in a magazine, and then in book form. The second edition has more new matter, gathered since 1877, when the first one appeared.

The work is a standard one. Mr. Cooper, the author, has been some little time on this coast, and is now employed in one of our large and growing manufacturing establishments. All who have seen the first edition of his work on belting know its practical character.

THE NEW PLACERS.—Mr. W. T. Simpson, who has just returned to San Francisco from the Cœur d'Alene mines, writes to the *Call* to say if people who think of emigrating there know when they are well off they had better stay in California, for there is extremely cold weather and over five feet of snow, and provisions are very high; \$60 a hundred for flour, and other things in proportion. There will be nothing done till the middle of April, and unless parties go in before the snow melts in March, they cannot get in until May or June, on account of the floods. Whoever goes has blankets to pack and a good buffalo robe to keep out of the cold, and they must knock up a log hut to live in.

Ratbdrum is the best starting point on the northern road, as from it there is an old road to the fort, and provisions, etc., are cheaper. I might say there are men wintering all along the road, waiting till the weather is milder to make a break in. There are thirty thousand people expected to go in this spring. All the men discharged from the construction department on the N. P. and the O. R. & N. are talking of nothing else save the mines. There must be a thousand in Portland alone that can get no work, but who are waiting patiently. There are about 500 or 600 on Frichard and Eagle creeks, and they have taken up ten and twenty acres apiece of government land, so we will not be surprised to hear of big shooting and bloody work in the Cœur d'Alene mines.

ASSAY BY AMALGAMATION.—This is for working results. Take any convenient quantity of the ore powder, add water enough to make a pulp, and heat it. If gold ore, add about 1-40th per cent of cyanide of potassium. If silver ore (not roasted), add 2 per cent of salt, and such other chemicals as may be desired in such proportion as can be profitably used on the large scale. Grind with pure quicksilver for several hours in iron mortar or Buck's amalgamator. Separate the pulp from the quicksilver by washing (panning). If good ore, distil the quicksilver or dissolve it in dilute nitric acid. The gold will remain. If silver ore, strain the quicksilver through a piece of wet buckskin. (Twist the buckskin so as to press the quicksilver through.) Tie the amalgam in a bit of cotton cloth, put it in a dry-cup and heat to redness in the muffle. Collect the metal, gold or silver, wrap it in sheet lead, cupel, part, weigh, and calculate results by percentage.

This extract is from a simple, practical work on "Assaying," by Chas. H. Aaron, now issued and for sale by Dewey & Co., San Francisco. Price, \$1.

If you want a lubricant that will run any thing cool write CHARLES J. WOODRURY, GENERAL MANAGER LUBRICATING DEPARTMENT CONTINENTAL OIL AND TRANS. CO., for "Lubricite." It is the best compound grease in the market. Shipped in 5, 10 and 25-pound cans, half barrels and barrels. Warranted to give satisfaction. Observe the numbers: No. 2 is soft for outside work; No. 3 is medium soft; No. 4 is medium hard; No. 5 is very hard, where unusual lubrication is demanded. Send for Catalogue of Lubricating Oils.

THE mining interests of Sonora, Mexico, are delayed by the imposition of a tax of three per cent on the export of all ore by the State government. Strong protests have been forwarded to the government on this matter.

Proposed Changes in the Land Laws.

A dispatch from Washington says: The subcommittee of the Senate Committee on Public Lands will probably recommend a number of radical changes in the homestead laws. Among them it is proposed to give a homestead claimant one year from the date of entering the land to establish a residence thereon, requiring, however, in the meantime that he shall break and prepare for cultivation a given area of land to establish the good faith of his professions. Under the existing laws he is required to go upon the claim and make it his home within six months of the date of entry. It is further proposed to admit homestead claims to final proof and patent only at the end of seven years from the date of entry, the present term being five years. It is argued that to an honest claimant, who farms the land for his own use, it is of little consequence when he receives a patent, since the entry of the land confirms him in every right but selling it, which he secures by a patent.

As a new feature of the homestead law, and a substitute for the timber-culture law, it is under contemplation to require that within the first four or five years from the date of entry every homestead settler shall plant a specified small area in trees, having previously taken such necessary steps to secure their thrifty growth as is now required by the Timber-Culture Act; this requirement being applicable, of course, only to treeless regions. The reason for grafting a portion of the timber-culture law upon the homestead law is found in the fact that under the former the land usually falls into the hands of non-residents, who have no interest in the cultivation of trees, and whose steps to that end are merely sufficient, under the law, to hold the land until it can be sold to advantage.

But little attention has yet been given to the pre-emption law, but there is better reason for expecting radical amendments than its repeal. The chief amendments suggested in committee look to a prevention of speculation by requiring that relinquishments shall not be accepted by local officers, and that when accepted by the Commissioner the land shall be open for entry by the first applicant, and that two years' actual residence shall precede the purchase of land.

THE OVERLAND MONTHLY.—This sterling home magazine shows continued improvement. The contents of the February number are attractive: "A Shepherd at Court," Chapter VII; "Thought and Speech," Caroline A. Mason; "Notes on the Frazer River," Henry Colbath; "Thomas Lodge and his Friends," Chas. Howard Shinn; "Mirage," A. S. R.; "Aunt Jane in San Francisco," L. J. Dakin; "Cruise of the Ocean Spray," I. M. Baltimore; "February Day on the Columbia in the mountains," H. S. Lyman; "New Japan," Shosuke Sato; "Incident in the Life of a California Detective," "Winter Sunset," M. F. Rowntree; "Chinese Slavery," H. Latham, M. D.; "Through Central Mexico," O. M. Wozencraft; "The Brahmo Somaj, or Protestantism in India," Horatio Stebbins; "The Late War in South America," II. Holger Birkedal; "Ametta," Chapters XXIV, XXV, Evelyn M. Ludlum; "Love's Coming," Thos. S. Collier; "In the Afterglow," "Oregon," In the Etc. and brief articles are: "Law Enforcement," "Japanese and Oriental Women," "A Village Anecdote," "Old Jim." The usual book reviews are given also. The number is one of considerable interest and literary merit.

The Supreme Court of this State has decided that when an owner first begins his assessment work for the year on the 31st day of December, and resumes again at or by 7 o'clock of the morning of January 1st, and continues from day to day till \$100 worth of work has been done for the preceding year, no re-location of such ground will hold good. The fact of the owner of the ground doing work as described is considered sufficient to keep his title good.

THE MINING AND SCIENTIFIC PRESS, of San Francisco, one of the most valued of our exchanges, in its issue of the 19th January last gives a full review of the mining States and Territories for the past year, as well as the text in full of the decisions of Judges Sawyer and Deady in the "mining debris" case. The number is invaluable to miners, and should be purchased and read by all.—*Rio Grande Republican*, Jan. 26.

THE hulk of the steamer *Senator*, which ran on the Sacramento river in 1850, will go into the dry dock within a few days, preparatory to being turned into a temporary harkentine, so as to enable her to sail to New Zealand, where she is to be used as a barge by an Auckland corporation.

A SURVEYING party has arrived at Bakersfield for the purpose of locating the route for the railroad extension from Soledad to a junction with the Southern Pacific in Kern county. The *Californian* thinks active work on the extension will be commenced early in May.

Lost Papers.

If any subscriber fails to receive this paper promptly, after making due inquiries at the Postoffice, he is urgently requested to notify this office by letter, that we may send the missing papers, and, if possible, guard against further irregularities.

Mining Share Market.

Mining stocks are not very active. Attention has been turned to Bodie of late more than elsewhere, and there has been a sort of Bodie boom. Our stock tables show the fluctuations. Up at Gold Hill the low stage of water in the Carson river still retards all ore extraction, except that required to keep going the few stamps that can be run.

At the Alta the east drift on the 2,100 level is being pushed ahead as rapidly as possible for the ore body, and all other work is progressing favorably.

At the middle mines all is now going on well. The new hydraulic pump is doing excellent work, and the Chollar-Norcross-Savage shaft is now being sunk to the 2,800 level as rapidly as possible. The sinking will be continued to the 3,000, but at the 2,800 level a station will be opened, and a drift started to the west.

The *Virginia Enterprise* says: In the Union Consolidated the main north and south drifts are now fast nearing each other. The men working in the two headings can now very distinctly hear the sound of the drills. This will be a very important connection as it will form an air gallery and base of operations on the 3,100 level from the Ophir on the south to the Sierra Nevada on the north. Once the connection is made, new life will be seen in the north end mines. Prospecting drifts will be started both east and west in the Union Consolidated and Sierra Nevada, and operations will be resumed on the 2,900 level and at other interesting points in the Mexican.

LOWERING PUMPS.—Sinking the main shaft of the Contention mine, Tombstone, had to be stopped for a time, waiting the arrival of large screws from San Francisco, with which to swing the working barrel and drawlift of the pumps, the formation in the bottom of the shaft being so soft that the working harrel of the pump buries itself whenever the ground is moved about its base. The *Epitaph*, in speaking of the subject, says that this working harrel is 200 feet in length, made in sections of very heavy castings, and contains, when the pumps are at work, 30 tons of water. This, with the enormous weight of the 200 feet of working barrel, makes a load that it is difficult to support. The screws for this purpose will be 15 feet in length and 3 inches in diameter, with a very heavy thread, and will be placed upon a station built for that purpose, one on each side, and passing through a heavy collar made fast to the working harrel. By this means the pump may be lowered a few inches at a time with ease and safety. The water in the shaft has been easily controlled for the last few days, the pumps making 4½ strokes per minute. As soon as the arrangements for supporting the pumps are completed, sinking in the main shaft will be continued.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

JOHN MUIR, Superintendent of Traffic of the Northern Pacific road, has resigned, to take the General Managership of the Oregon Improvement Company for a term of years. He will reside in Portland, and will attend to the entire Pacific coast interests of the company, including their railroad and steamship lines, and coal interests.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

B. W. CROWELL—Nevada.
I. M. LEHLY—San Bernardino and San Diego counties.
J. J. BARTELL—Sacramento county.
C. E. CURTIS—Kern and Fresno counties.
A. S. DENNIS—San Mateo county.
A. C. KNOX—Tehama, Yuba and Yolo counties.
Wm. R. McQUIDDY—Tulare county.
F. M. THILMAN—Fresno county.
ED. MACK—Santa Clara county.

Job Press for Sale or Exchange.

We have just received a new improved Rotary Job Printing press of approved style and make, which we will sell at a bargain or exchange on favorable terms for a Washington hand press. Size of chase inside 7x10 inches.

DEWEY & CO., publishers.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUME OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

IMPROVED FORM —OF— HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above out of an improved form of Hydraulic Giant, in which it will be observed that the De-lec-tor and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "backing," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled P. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville Foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

JOSHUA HENDY MACHINE WORKS,

49 and 51 Fremont Street,

San Francisco, Cal.

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the so-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the "Triumph," and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the "Triumph," or any other machine, for stakes of \$1,000.

Steam Engines and all Kinds of Mill and Mining Machinery.

GIANT POWDER,

MANUFACTURED UNDER ALFRED NOBEL'S Original and only valid Patents for NITRO-GLYCERINE Powders, which has been and still is of such immense advantage to the Miner, Railroad Man and the Engineer. All other Nitro-Glycerine Compounds are simply imitations and adulterations of the Original Giant Powder. The GIANT POWDER COMPANY manufacture three grades of Powder, which are the Safest and Strongest High Explosives in the market. The Original Nitro-Glycerine Compound, GIANT POWDER or DYNAMITE, is acknowledged by all the great chemists of the world as unapproached by any other compound. The GIANT POWDER COMPANY have acquired the exclusive right to manufacture "NOBEL'S EXPLOSIVE GELATINE," which contains 96 per cent of Nitro-Glycerine. It is still stronger than Dynamite, and even safer in handling. This explosive was used in constructing the Mont Cenis Tunnel. THE JUDSON POWDER is a black Powder owned and Manufactured by the GIANT POWDER COMPANY; is from three to five times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it Breaks More Ground, Pulverizes Better, and Saves Time and Money. The only difficulty heretofore experienced by some consumers of this Powder has been that it required more time to get it to the bottom of a deep borehole. This has now been entirely overcome, and our JUDSON IMPROVED is now as dry as the ordinary Blasting Powder and runs as freely.

Triple, Quadruple and Quintuple Caps and all grades of Fuse for Sale.

Geology of Eureka District.

A short time since we gave a brief abstract of a report by Arnold Hague, on the geology of Eureka district, Nevada. The district is one of great economic interest, as the seat of active mining industry, and has been as well the center of immense volcanic action. It was therefore judiciously selected for very careful mining and study. The monograph of Mr. Hague for the United States Geological Survey is purely geological in its character, and is certainly a careful study of a comparatively small block of mountains, which may be called the Eureka mountains. It is not Eureka district

Hamburg limestone, and SC for Secret canyon shale; PL for Prospect mountain limestone, and PQ for Prospect mountain quartzite. In the Igneous, B is for basalt; R for rhyolite; T for tuffaceous and tuff; A for augite and andesite, and HA hornblende and andesite. The base line of sections is 6,000 feet above sea level.

Section C'D-EF is constructed across the central portion of the Eureka mountain, and therefore presents more of the principal structural features of the region than is shown in either the northern or southern sections. It is drawn through Mahogany hills, Spanish mountain, Prospect ridge, Spring hill and County Peak group, and crosses the Spring valley, Hoosac

follows up New York canyon as far as the reservoir, where it turns and runs south until lost in the quaternary deposits of Fish Creek valley. As the line of the fault has been the center of volcanic action, its outline can only be traced approximately inasmuch as it is almost wholly concealed by extensions of horn blende-andesite and rhyolite, the former variety only appearing on the line of the section. Beyond this narrow belt of andesite comes in the lower coal measure limestone, dipping at first to the eastward, followed by a synclinal fold, which is abruptly cut off by the Pinto fault, beyond which the Lone Mountain silurian of the County Peak group

the Lone mountain silurian. The section shows, then, two parallel displacements of not less than 13,000 feet, which, in the neighborhood of Spring hills, are nowhere more than two miles apart. Continuing along the line of the section east of the Pinto fault, the Lone mountain limestones are partially exposed, followed by a great development of Nevada Devonian, measuring 4,500 feet across the middle and lower beds, and well characterized by organic forms. At Basalt Peak igneous extrusions conceal the sedimentary beds, but the section is constructed from exposures observed both to the south and east, and may be readily understood by reference to the map. Section GH-IK

GEOLOGICAL SECTIONS OF EUREKA DISTRICT, NEVADA.

alone, as several other districts are in this mountain area.

By reference to the accompanying cross sections, the broader structural features of the mountains of the Eureka district will be readily understood.

The lines of the cross sections have been accurately constructed along carefully selected east and west lines. The sections are a reduction from the large double plate in the atlas, which forms a part of the final report, and are drawn on a scale of 3,600 feet to the inch, with the base line taken at 6,000 feet above sea level, the height of the adjacent valleys.

The letters on the sections refer to the geological periods. The Q is for mountain quaternary; VQ for valley quaternary. In the carboniferous, C is for upper coal measures; W for Weber conglomerate; LC for lower coal measures; DP for Diamond; PK quartzite. In the Devonian, WP is for White Pine shale; D for Nevada limestone. In the Silurian, S is for Lone mountain sandstone; K for Eureka quartzite, and P for Pogonip limestone. In the Cambrian, HS is for Hamburg shale; H for

and Pinto faults. The section intersects Prospect ridge just to the north of the summit of Prospect Peak, and brings out the anticlinal structure in the quartzite on the west slope overlaid on both sides of the fold by the Prospect mountain limestone, which to the east forms the summit of the main ridge. This is in turn overlaid by Secret canyon shale, Hamburg limestone and Hamburg shale, the remaining subdivisions of the Cambrian, all of which stand inclined at about 70° to the east. As the section is drawn across quite a high saddle at the head of New York Canyon, connecting Prospect Peak and Hamburg ridge, the erosion of the Secret canyon shale is not so well shown as it would be if the section were drawn either to the north or south of this point, but is quite sufficient to bring out the prominence of the Hamburg ridge, which is everywhere parallel to the main mountain. Overlying the Hamburg shale occurs the Pogonip limestone and Eureka quartzite, which occupy the long slope down to the Hoosac fault. The Hoosac fault extends along the base of the ridge approximately parallel with its trend. It

starts in along the southwest base of Richmond mountain, and runs southward just east of Hoosac and English mountains, and, like the Hoosac fault, is finally lost in Fish Creek valley, two faults being roughly parallel in their trend.

Between the two faults the thickness of the carboniferous limestone, where it has been best observed, has been estimated at 3,500 feet. If uppermost beds on the west side of the Hoosac fault belong to the summit of the Eureka quartzite, and the base of the lower coal measures is exposed on the east side of the fault, then the amount of displacement would be measured by the combined thickness of the Lone mountain limestone, Nevada limestone, White Pine shale and Diamond Peak quartzite, which in the general section is given at 12,800 feet. As a portion of the carboniferous limestone has also been carried down, it may be assumed that the vertical displacement amounts at least to 13,000 feet, or nearly two and one-half miles. The displacement along the Pinto fault is even greater, as along the Carbon ridge the overlying Weber conglomerates are brought down against

is drawn across the southern end of the mountains in a continuous line from west to east, passing through Gray's peak, Gray Fox peak, Carbon ridge and Resene canyon. The only Cambrian rocks found at the surface are the Prospect mountain limestone, the overlying epochs, together with Pogonip limestone and Eureka quartzite, being buried by flows of rhyolite. Between the Hoosac and Pinto faults the section again crosses the carboniferous block, which here includes a portion of the Weber conglomerate, as well as the lower coal-measure limestone, both members lying inclined at angles varying from 60° to 70° to the eastward.

The two epochs of carboniferous limestones are nowhere better shown in the district than along the line of the section. The lower limestone dips uniformly to the west at an angle of 25° to 30°, with a development of 3,700 feet of beds, overlaid by the Weber conglomerate, 2,000 feet in thickness, showing a synclinal and anticlinal fold, beyond which come in the upper coal-measure limestones, but only represented with a thickness of 500 feet.

CORRESPONDENCE.

Paradise Valley and Paradise Mines.

[From our Traveling Correspondent.]

EDITORS PRESS:—Winnemucca, the county seat of Humboldt county, on the C. P. R. R., 90 miles east of Reno, is one of the most prosperous of the Nevada railroad towns. It has on the Humboldt river and other valleys hay and grain lands and a large scope of good stock country to support it, besides some good mining districts also tributary. To the railroad passenger the town is almost entirely hid, and most of those passing have no suspicion of the existence of a town of 673 inhabitants, a nice long business street and the different streets of neat dwelling houses that are about a quarter of a mile from the depot.

The Humboldt river makes its serpentine course down the valley, and, like all Nevada rivers, reserves the right to sink below the surface occasionally. From Winnemucca by the stage road, over some rolling uplands for twelve miles, you reach the first dwelling, a stage station, post-office and toll-house, the toll being for sage-brushing a few miles of sand drift, that would be very heavy were it not thus bridged or littered with the brush and lumpy bark of the sagebrush. A short distance beyond this dividing ridge we enter Paradise Valley. The name sounds lovely, and there are seasons when this is not entirely a misnomer. The valley is thirty-five miles long, and an average of one to five miles irregular width. It is considered here a thickly settled valley, partially irrigated, and many nice tracts of well fenced lands producing alfalfa, barley and wheat. The alfalfa gives good satisfaction as a profitable forage crop; the natural grasses produce good crops without any plowing and sowing.

The Best of the Valley Lands

Are enclosed generally with barbed wire fences. Some of the San Francisco meat merchants have fine outfits here for supplying their stalls with the very choicest young stock. Though the raising and fattening of cattle seems to be the great business, it is not at all the exclusive business, as the two flouring mills of the valley can testify to a large amount of wheat and barley being raised, the "Farmers' mill," capacity 12,000 pounds daily (water-power), on Little Humboldt river, under the charge of R. C. Pennington, turning out excellent flour, judging from the choice bread I ate in the valley. The upper portion of the valley is favored also by another water-power flouring mill of similar capacity belonging to S. B. Pierce, who is also quite a successful farmer and stock man. He has made very good success in his orchard experiments. He brought out some very fine specimens of several kinds of apples, some very large pippins, good greenings, Bellflowers, etc. Hungarian prunes and plums did well; cherries bore well, but the birds would scarcely trust them to ripen. Bartlett pears, currants and gooseberries thrive well. Mr. Pierce had no trouble to sell his apples in the neighborhood for six cents per pound. This valley has a few places well adapted to some berries, currants and a few fruits, but it is frosty generally, and fruit is in danger of being nipped by late frosts.

The residences of the valley are generally quite neat and comfortable—with schools where needed. The village of Paradise, the business center of the valley, is a neat town of about half a dozen stores of a general assortment order, mechanics' shops, two good hotels, and about eight saloons, one good public school with two teachers, but no church. The whole community seemed much interested in some kind of Christmas celebrations; though the weather was quite stormy, there were no postponements. I found the farming people very pleasant, and more happy because their thoughts were much engaged in plans to make others happy. I thought one element that helped the buoyancy of the holiday season was the great

Success of the Paradise Mines.

Situated about 8 miles across the valley in the edge of the mountains.

In 1863 or 1869, the Wild Goose and Paradise mines were located and the district named "Mount Rose" after the huge ledge of red quartz that outcrops fifteen to twenty feet along the crest of the mineral ridge. Considerable ore was taken out—the first was shipped to Salt Lake and Rye Patch for treatment. A small mill was built. The estimated output from the Paradise mine was not less than \$500,000, and some say fully \$600,000, this from a ten-stamp water-power mill. The Bullion mine, with a ten-stamp mill (belonging now mostly to Charles Kemler, merchant of Paradise City) produced about \$350,000 previous to the burning of their mill on November 18, 1883.

The Bullion is called a good mine, being the first extension of the Wild Goose mine, on the south. It is not yet prospected to the depth of 125 feet; it now lies idle, as its owner is fully engaged in other pursuits, who is not a practical miner nor milling expert. The Bullion mill is about three miles from the mine, at the edge of Paradise valley, and has a graded road to the mine.

Wild Goose and Paradise.

Passing this, the next claim on the same grand ledge is the "Wild Goose," and below it the "Paradise mine," a parallel vein, lying 700 ft.

to the east. These two locations, through the perseverance of Mr. J. V. McCurdy, an old Virginia City expert of more than 20 years experience, succeeded in uniting in one corporate company of 100,000 shares. I use the term perseverance, in the fullest sense advisedly—for these mines had been lying idle for two years ("Worked out;" "got no ore in sight," "only surface paying mines.") Mr. McCurdy carefully examined them and undertook the task of convincing the owners, that instead of being worked out, they had not yet had good, earnest prospective work done, and that he saw right there the fullest assurances of a paying mine, at an insignificant amount of expenditure. He hunted up the scattered owners, and set forth to their slow and unwilling comprehensions a programme with the fullest assurances of a quick and ample success. But before he would get around to all the owners, those first converted to his faith in the mines' value, and his plans for making this wealth available, would, many of them, become backsliders, and want to rest quiet yet, for fear they would spend some "good money," and not see it return promptly.

A prominent citizen and farmer remarked to me, "I consider Mack the persevering man of a thousand; for not one of a thousand would have labored with us as he did to convince us that we had a good property, and then to put it in a business shape, and do more than ever he promised in speedy results."

There are interesting points that might be mentioned in this preliminary organizing work, but suffice it to say it was successful; and after seeing the principal part of those interested in the business, I can say they each had one uniform tone of praise and satisfaction in the present management. Last August Mr. McCurdy took possession of the mines: no ore in sight; mill to be repaired and changed to do better work than before; the ditch to be repaired and the dam to be made anew; and to save continuous expense and delays he used a large amount of Portland cement in the dam construction, so that a few thousands of dollars (\$8,500) debt was incurred before the mill was ready and furnished with ore. The August expenses, for running and repairs, exceeded the yield about \$2,500, making a debt of over \$10,000 to be liquidated, and to test the faith of the weak ones concerned. A small crop had now been platted, and since then the harvest has been going on. The Wild Goose yielded for the month of November \$21,000; the November shipment was \$22,273 and the December \$25,000. Since then the 10 stamps have been turning out about \$1,000 daily on average unassorted ore (about \$100 per ton.) The mines look very encouraging. They have now a body of pay ore 14 feet thick in the Paradise, and have struck the same body below 75 feet. The ore is good milling—without assorting showing nice specimens of native silver all through it.

The Wild Goose has one level 225 feet below the surface; have raised above this 75 feet and opened another level there, and raised 35 feet above that, and the ore holds still the same as below, and 8 feet thick, and in the lower drift have opened the vein for 100 feet without a break in the pay ore—here is a ripe harvest of stopings, that if situated at some distant and inaccessible point would make a fine sensation. But here, near the railroad, in the midst of a good agricultural and stock settlement, it is scarcely noticed; and this seems to be the choice of those concerned that but very little notice shall be attracted thither for the present. These mines are

Not Considered at all Developed.

But only a small prospect work started and now carried on by a man without any capital except a long mining and milling experience, coupled with an energy, backed by good judgment and confidence, that would not recognize defeat though claimed by a multitude on the outside. A tunnel 600 or 700 feet will tap the ledge at a depth of 500 feet, and when run on back will tap the Wild Goose at still greater depth, and deliver all the ore at the ore chutes for loading in the wagons at the roadside, thus dispensing with costly hoisting machinery for a long time. The situation of the mines for cheap and convenient opening is very advantageous, and the eight miles of road to the mill is nearly all a moderate down grade.

The year 1884 has recorded already the Paradise Company as one of the dividend paying stocks, and that on a true and genuine basis of production, and not from stock sales or assessments collected. Here is a district

To be Heard From in the Spring.

As I am told many relocations have been made, and old locators have carefully been looking to their sleeping, undeveloped claims, some of which promise well. The Paradise mill has both steam and water power that can be used together or separate as desired. When the water is full head it is ample power, but when only half a full head it lessens very much the expense of fuel for the steam power. The mill is a model of convenience, and quite efficient for the free milling ores—that will probably last long enough to wear it out before they are exhausted—by reaching the change at water level. The tailings are all passed over blanket concentrators, and the heavier portions safely piled up exposed to the sun and air for future workings. There is a system of care and economy apparent everywhere about the works; supplies of salt, ore, chemicals, wood, hay, etc., on hand, so that in case of a prolonged storm, teams need not be exposed nor the mill

obliged to stop. The Superintendent is himself a large owner in the stock of the company, and has a special interest in its success.

Other Mines.

The Red Deer, owned by an Eastern company, is considered a good property, though they are at present only doing assessment work.

The Live Yankee, owned by Nick Freyer, is said to have plenty of good low grade—i. e. \$50 to \$80 per ton.

Oro Cash, owned by Dr. Powell and Wash. O'Neal, has a small development, with good prospects.

The Rattler, owned by Marcott and Brannan, practical workers, has high-grade ores and very encouraging prospects. A carload worked in Salt Lake yielded \$540 per ton. They have shipped some as good to San Francisco works.

Various extensions of the good mines are showing good indications of future value. The district lacks men of capital and more facilities for cheap reduction. Rich men and railroad chiefs are very naughty on general principles, but they are very handy to help start up new mining camps and convert them into bonanzas.

Other Districts Waking Up.

South of Paradise—same range in Colconda district in the Eden mountains—are several promising claims held mostly by poor men, who do prospect work from year to year sufficient to hold till something will turn up to relieve them. The veins are generally large, carrying low-grade ores seldom over \$80 per ton, yet some of the smaller veins mill as high as \$200, as is the case with first-class Silver King ore. Not many claims are now worked; wood and water are scarce. Mr. Sadorus, Sr., owner of the "Credit Mobilier," is said to have a good mine tunnel in the 200 foot shaft down 71 feet. He has got some specimens of coarse gold, also fine gold. He has a small rotary battery. His claims are within the Paradise district boundary. Humboldt county will soon be as well known for her bullion yield as she now is for her great beef shipments.

B. W. CROWELL.

The New Copper Assay.

EDITORS PRESS:—I have just met with an illustration of the value of my new method of assaying copper, which may interest your readers.

I had a sample of ore to assay for silver and copper. Being somewhat pressed for time I made the assay for copper by the potassium cyanide method with newly prepared and titrated solution. This gave me 8.7 per cent copper, the assay passing perfectly. With a view rather to testing the new method than checking the assay, I tried the former. It gave me 1.7 per cent by a rather hurried operation. This great discrepancy led me to make a third assay by the Swedish method, which passed unusually well, the copper running down in a thin but compact sheet which separated well from the iron. I got 2.2 per cent copper, which, redissolved and titrated by the new method, gave 2.3 per cent. In this instance the operation was performed in too small quantities, only 50 ins. of copper being used for the titration. The zanthate solution used was a month old. I have since worked with stronger solutions, using one gramme of copper for titration, that quantity requiring about 200 cc of the zanthate solution. I have no hesitation in saying that, working in this way, the method is more exact than the hurried assay of silver bullion with the same weight of metal.

On examining the ore spoken of I found that it contained a considerable quantity of zinc, which doubtless caused the enormous result by the cyanide method. The zinc being in the state of oxide was not very apparent to the sight.

One great advantage of my method, besides its delicacy, is the facility with which the presence of nickel is detected, this metal frequently occurring with copper. It is only necessary to add acetic acid in excess to the ammoniacal solution from which the copper has been precipitated, and then a little more of the zanthate, unless it was previously used in excess. If a trace of nickel is present a yellow color is produced; if more than a trace, a yellow precipitate soluble in ammonia.

C. H. A.

January 31st, 1884.

Prescott, A. T.

The Volcanic Period Prior to Man's Creation.

EDITORS PRESS:—We have evidences, more particularly on the American Continent, of a period of extraordinary volcanic activity, of which the basin of the Pacific Ocean is the theater, that occurred in the latter tertiary. Since that time the earth has been comparatively quiet with occasional spasmodic actions, and the forces of nature have had twice to recuperate their strength.

This volcanic outburst occurred at a period subsequent to the formation of the deep placers, or what now are known as ancient river channels or "Dead rivers," in the Sierra Nevada mountains.

During that time the whole western slopes of the North American Continent, particularly that portion near the Pacific Ocean, must have been the scene of an intense volcanic activity of which we have unmistakable evidence in the upheaval of the coast range of mountains, the elevation of the Sierra Nevada, with the

summit studded with volcanic cones and its westerly slope with lava-covered beds of ancient river channels—valleys, which previous to the upheaval, were the bed of the ocean, filled for hundreds of miles in length and to a great depth with volcanic ashes, pumice, scoria and basaltic lavas. The usual phenomena accompanying violent and extensive volcanic outbursts doubtless were not wanting; the earth's surface undulating like a troubled sea; deep fissures and chasms opened in the solid rock through which molten lavas, thermal waters, sulphuric and mephitic vapors, electric and inflammable gases were constantly emitted; mountains rent in twain; rivers turned from their courses seeking new channels; lakes dried up, or their waters disappearing in yawning abysses which were opened to receive them; new lakes were formed, and the whole configuration of the country changed. The shores of the Pacific removed some sixty miles westerly, its hitherto placid waters maddened and tossed by violent earthquakes, receding, surging and foaming in mountain waves, striving to surmount the new barrier and regain its lost ground and familiar shores; torrents of water and much pouring down the mountain sides from successive rains; sudden melting of immense glaciers and mountains of snow from the fervid heat of the lava flow, inundating the country. It was a war of the elements—fire vs. water—each striving to obtain the mastery. There were doubtless unearthly, terrific and appalling noises; dense clouds of ashes and volcanic dust obscuring the sun; a red, lurid and unearthly light seen, and at intervals spasmodic volcanic eruptions, lighting up the whole country with a light so vivid and intense that the sun would have paled had it been visible. Huge masses of molten rocks, hundreds of tons in weight, were thrown high in the air, their surfaces contracting on meeting the cooler atmospheric air, and exploding with deafening reports, scattering their thousands of fragments of bright, glowing masses of fire in every direction—a pyrotechnic display shaming man's puny efforts. Streams of molten lava were running down the mountain sides with irresistible force and velocity, cutting down extensive forests of mammoth trees with less effort than the farmer exerts in mowing his grasses, in its onward and downward flow, melting down hills and filling valleys.

Under all this superficial disturbance lay the motor, the irresistible and invisible power that produced this effect—one vast sea of molten lava and generated gasses contracting and expanding under the immense pressure of the superincumbent mass. The earth's crust was like the waves of the sea, convulsed and tossed about by the expansive forces of its highly-heated and elastic gasses, struggling to escape from the rocky embrace. This wreck of matter and trash of worlds must have produced an indescribable effect, and one that "Dante, with all his vivid and descriptive powers, would have made but a feeble attempt to portray." Dore, with his wonderful pencil, would not have been equal to the task.

This terrible convulsion must have been preceded by premonitory symptoms, affording time for many of the then existing animals to escape from the mountain ranges, as these "dead" or "ancient river" channels are nearly destitute of animal remains. That animals existed in immense quantities and of mammoth proportions at that time and inhabited these densely wooded forests with which the mountain ranges were covered we have abundant proof, as their fossilized remains are found at numerous places in the lower foothills and deltas, while the lava covered auriferous channels of the dead rivers are filled with fossil trees and vegetation, with but few animal remains. The then existing animals undoubtedly rushed in terrified, frantic and countless herds to the plains, seeking the cooler atmosphere of the sea, but to meet a frightful and horrible death from which there was no escape. They were either overtaken and engulfed by streams of molten lava, floods of mud and water, or destroyed by mephitic vapors and poisonous gases that extended over the entire continent. Should they have been so fortunate as to have reached the sea, the incoming earthquake wave engulfed and destroyed the survivors, its under-tow sweeping their remains seaward, and they became a thing of the past.

XMAN.

ARSENIC.—Arsenic is widely disseminated throughout the ores of the Rocky mountains, occurring principally in combination with iron forming the mineral mispickel. In Gunnison county, Colorado, it occurs in combination with cobalt and iron, probably as the mineral lollingite. On the Pacific coast the mispickel is frequently auriferous, and is treated by the chlorination and leaching process for the extraction of its gold contents. Mispickel is also found, in more or less quantity, in almost every portion of the United States; and is often mistaken by farmers for silver ore. Large quantities of arsenic pass off in the fumes from roasting and smelting furnaces and are lost, no attempt being made to save the volatile elements in the ores. Arsenious acid occurs quite frequently in fragile crystals in the dust chambers of smelters, forming beautiful specimens for cabinets.

NEAR Halfmoon bay, while the farmers are plowing, numbers of sea-gulls follow the plow, and now and then they swoop down and catch a field mouse, and, with a twist, it is at once swallowed. In this way thousands of vermin are destroyed.

MECHANICAL PROGRESS.

Solid and Gaseous Fuel.

In view of the large amount of attention that is just now being directed to the comparative value of solid and gaseous fuel, the following, from *Le Gaz Belge*, will be read with interest:

When solid fuel is employed, it is not only necessary to provide the supply of oxygen required for combustion, but also to convey into the furnace sufficient air to drive off the products of that combustion, by ensuring the contact of the oxygen with the whole surface of the combustible material. In practice it is found that nearly twice the quantity of air theoretically required has to be provided, and this, of course, doubles the volume of the gases that have to be heated. It may thus be assumed that half of the air admitted into a furnace does not serve for combustion; and this excess of air naturally carries off a considerable quantity of heat. The loss, however, is a necessity, for if less air were supplied there would be a possibility of combustion being incomplete, and the evil would become greater. In fact, the carbon passing into the condition of carbonic acid (the result of the most complete combustion) develops 7,200 heat units, while with a less perfect transformation it furnishes carbonic oxide, giving only 1,400 units. When gaseous combustibles are utilized, these losses may be prevented, since very nearly the determined quantity of oxygen may be supplied, and this be caused to mix more closely with the combustible elements, without necessitating the expenditure, on the part of the mixture, of an amount of energy comparable with that required by the solid combustibles.

The commercial value of the two kinds of combustibles may be approximately stated as follows: Coals have, according to their quantity, a standard of from 4,500 to 7,500—say an average of 6,000—heat units. From this number must be deducted 500 heat units lost in effecting combustion. There remain, therefore, 5,500 heat units. Now the absolute available heat of furnaces employed for industrial purposes does not exceed 40 per cent of their theoretical heating capacity, and, therefore, effective calorific power is reduced to about 2,000 calories. The cost of furnace coal of average quality ranges from 6 to 8 francs per 1,000 kilos—say 0.8c per kilogramme (2.2 pounds). The 2,000 calories heating power therefore cost 0.8c. If coal gas is taken as the element of comparison, its yield in heat being 12,000 units of the net cost of 7 cents, the ratio becomes 1.4 for coal gas respectively. This, however, is exclusive of the cost of labor, maintenance of appliances, transport of fuel, etc., all of which would double the net cost of the solid combustible material, so that the proportion really becomes 2 for coal and 1.4 for gas. But the solid combustible furnishes only 2,000 calories, while if it is transformed into lighting gas it would furnish 3,000 calories. The final ratio of the net cost, therefore, become 3 for coal against 1.4 for gas. In other words, the employment of illuminating gas as a combustible is attended with about twice the economy that results from the use of ordinary coal.

Working Cold Wrought Iron.

Unless the iron is of small diameter, as wire, and makes a considerable circle in bending, it is usually believed that it should be heated to be worked. But if the wire is of tough iron it may be worked as closely when cold, if not as easily, as though heated. Familiar instances are the small articles known as "bright wire goods." These are staples, hooks, rings, screw eyes for picture frames, angle hooks, and many similar articles. Some of these undergo as square bending as would be possible if they were worked when red hot, as the angle hooks, which are either pointed to be driven or threaded to be screwed; the angle being perfectly square without the suggestion of a curve. These hooks are made in machine dies, and to form the elbow with a perfectly square turn the wire is actually upset cold at the bend. Other instances of the malleability of cold wrought iron are given in the heading of cut nails and iron rivets, but usually this sort of work is kept within narrow limits as to size of material. Yet a large tool-making establishment in New England has built a number of heading machines on foreign orders that made conical and flat heads on bars of iron three-quarters of an inch in diameter. These heads were as clean and as free from cracks or fraying as if formed from the red hot bar, and the projection of the head on each side was slightly less than one-quarter of an inch, making a head one and a quarter inches in diameter. The heading machine for such work as this must, of course, be of enormous strength to resist the blow and pressure that would upset a three-quarter inch bar to such an extent.

Wrought iron has another quality when cold—that of being welded—a quality that in some instances makes trouble, but in others is utilized. Where iron washers have been put in the stop of an upright shaft carrying a heavy wheel with a view of dividing the friction, they have sometimes become welded solidly, so thoroughly united that not even heating them would separate them. Harness rings of iron wire and others for hand hags are solidly welded when cold by placing the formed ring in a die a

trifle smaller in diameter than the ring, and bringing a corresponding die with great pressure on the ring, forcing the ends of the wire together.—*Scientific American*.

DYNAMITE FOR ARTILLERY USE.—The *Norwalk (Conn.) Hour* describes a device for throwing dynamite cartridges instead of balls or shells from cannon for destructive use. That paper says: On the floor of one of the rooms of the Norwalk Iron Works Company is a long, heavy cylinder. Its length is about twenty-eight feet, and the diameter of the bore is about four inches. In another department men are at work constructing an air compressor. When the latter is completed it will be connected with the tube mentioned above, and what the inventor confidently believes will be a most tremendous engine of war will be complete and ready for trial. Several years ago, while in Washington, a gentleman from Ohio heard a naval officer say that if a gun could be constructed that would throw dynamite it would thoroughly revolutionize modern warfare. Mr. Millin—that was the gentleman's name—proceeded at once to invent such a gun, and he has reason to believe that it will be a perfect success. It would not do to use powder as a propelling power, for its sudden action would explode the dynamite cartridge at the start and blow the gun to atoms. Compressed air, at a pressure of about 300 pounds to the square inch, will take the place of powder, and the gun now in South Norwalk is expected to throw a three pound cartridge a distance of two miles. Imagine the effect of a cartridge of even so small a weight striking the side or deck of a vessel, or the ramparts of a fort. The explosion would be terrible in its results. If the gun is a success, others of a size sufficient to throw 100 pounds of dynamite ten miles will be constructed. The gun, loaded with sand instead of dynamite, will be tested in South Norwalk at an early day, in the presence of naval officers, scientific men and others.

THE IMPORTANCE OF THE MECHANIC.—Each ensuing day, says the *Boston Commercial Bulletin*, makes more prominent the fact that we have come upon the time when the mechanic is master. We have crowded professions and ill-filled trades. A chance to fill the position of sub-assistant clerk in a wholesale house is eagerly grasped at by a hundred applicants, though the wages received be scarcely more than "a chance to learn the business." Let a master workman try to obtain an apprentice at three times the salary offered the clerk, and his applicants will be poor alike in quantity and quality. A skilled workman in any trade need never want for hire; he is eagerly sought after by a hundred employers; he is independent of the condition of the market; the skill and cunning of his hand and eye are too valuable to lose, and must be paid whether the products are slowly or rapidly consumed. If business ceases, the master hand is eagerly seized by some rival house, which knows and values the product of his skill. He who would crush down the obstacles to success in our own days must have, as well as the wit to see the crevice, the strength to deal the blow. This is an age of the steam engine, and it is the engineer, not the conductor, who is master.

A DIFFUSION ENGINE.—A curiosity in physics was exhibited by Mr. Woodward, lately, at the Physical Society, London, in the shape of what is veritably a diffusion engine; that is to say, a machine in which work is done by the diffusion of gases. The action of the engine is based on the experiment of the late Prof. Graham, the well known chemist. The experiment consists in taking a red clay porous cylinder containing air and covering it with an inverted bell-jar full of hydrogen. The hydrogen diffuses into the cylinder more quickly than the air diffuses out, as shown by means of a glass tube projecting from the bottom of the cylinder into a vessel of colored water. When the gaseous pressure inside the cylinder is increased by the influx of hydrogen, the mixed gases descend this tube and bubble out of the water. On removing the bell-jar the action ceases, and a reaction, due to fall of pressure, causes the water to rise in the tube. By suspending the gaseous cylinder of porous clay from a balance beam, and directing a jet of hydrogen gas against its side, the beam begins to oscillate and keeps plainly oscillating for a length of time, the action being sustained by the alternations of gaseous pressure in the cylinder.

NEW SPIKE.—A railroad spike has just been invented by Wm. H. Bailey, of Minneapolis. It is a common spike twisted to form a spiral, and it has a small spur at the point to facilitate its entrance into the tie. When driven, we believe it will hold like a screw; but if it turns in going inward it will be difficult to hit the head on to the lip of the rail.—*Lumberman's Gazette*.

A PROCESS FOR FROSTING GLASS.—To give glass this appearance, it is only necessary to coat it with the following composition: Sulphate of magnesia diluted in beer, with a little dextrine added.

AMERICAN CARS IN ENGLAND.—The Midland R. W. O. will hereafter build all its cars on the American model, and its Pullman cars for first-class passengers, without extra fare. The world moves.

SCIENTIFIC PROGRESS.

Origin of the California Coast Mountains.

Are they the Results of Glacial Action, and not of the Uphenavni?

Quite an interesting discussion occurred at a late meeting of the American Association for the Advancement of Science, respecting the geological changes which were brought about by the movement of ice during the glacial period.

Some of the members declared that they did not believe that glaciers have ever been an important geological agent, and that the phenomena usually ascribed to glacial action in the record of an ice period were generally due to icebergs. While, on the other hand, others asserted that during the glacial epoch heavy ice sheets covered most of the elevated portions of western North America, as far south as the 36th parallel of latitude; and that eastern North America was overspread with ice, which attained a depth of between 5,000 and 6,000 feet. This last declaration supports the views of Professor Hitchcock and others, who believe that the ice sheets of New England were able to move their debris over wide lands of little declivity towards the sea, their immense deposits forming the lands of Cape Cod, and also the large islands of Nantucket and Martha's Vineyard. Glacialists also maintain that even greater work has been performed by ice sheets in other countries.

Professor James Geikie stated in his discussion on the glacial deposits of northern Italy, that the deposits from Alpine ice sheets of a frigid period "rise out of the plains of Piedmont as steep hills to a height of 1,500 feet, and in one place to nearly 2,000 feet. Measured along its outer circumference this great moraine mass is found to have a frontage of 50 miles, while the plain which it incloses extends some 15 miles from Andrate southward."

Prompted by the above discussion, a correspondent of the *Scientific American*, Mr. C. A. M. Taber, of Wakefield, Mass., communicates to that paper the following views as to the work performed by glacial action on the Pacific coast. Notwithstanding Prof. Whitney and other geologists declare that the

California Coast Range of Mountains

Has been produced by great disturbances and upheavals within a comparatively recent geological period, Mr. Taber says that from his observations while traversing that region: "It appeared to me that the Coast Ranges originated in a different manner from the older Sierras. The western sides of the latter mountains everywhere showed the great eroding power of ancient glaciers; and when I consider their favorable position for the accumulation of snow during a glacial period I was led to seek for the glacial deposits adequate to represent the great gathering of ice which an age of frigid temperature would produce. But it seemed to me that such deposits could not be found in the foothills of the Sierras, which contain the moraine of inferior ice sheets that terminated at the base of the mountains. Under these considerations, I came to the conclusion that during the earlier ice periods the immense glaciers which formed on the western slopes of the Sierra Range moved their gigantic heaps of debris so far seaward as to form the range of hills now existing next to the coast line; the Contra Costa, or middle range, being formed during a subsequent ice period in the same manner as the hills next to the coast line. Still, it may be that neither of the Coast Ranges was the work of a single ice period, but the western range must necessarily have been the earliest deposit.

"Although the Sierras differ from the coast hills in composition, it does not disagree with the glacial origin of the latter region, from the fact that the ice sheets while moving their bulk westward displaced the deposits of such bays, lakes, rivers and marshes as lay abreast the Sierra slopes; the moving ice-sheets, thousands of feet in depth, pressed and plowed below the somewhat superficial Cretaceous and alluvial strata which lay in its course. The disturbed strata, while pushed along in confused heaps in front of the ice, were amassed in ridges sufficient to form the hills of the Coast Ranges. The boulders found imbedded in several of the coast hills must have been moved by ice from the Sierras, on account of the Coast Ranges not having a rocky core of sufficient firmness to give shape to such boulders. Moreover, the temperature of the Pacific waters would not be favorable for glaciers to form on the Coast Ranges with the ice-sheets of the Sierras terminating at the foothills.

"The Sacramento and San Joaquin valleys are now covered by recent river deposits, therefore the glacial drift which should be traced from the Sierras to the Coast Ranges is concealed. But the abraded appearance of exposed solid rock at the base of the foothills, and also the scattered boulders which gradually disappear beneath the diluvial deposits of the plains, indicate that the Sierra ice-sheets could not have ended at the foothills, but must have moved further westward while pushing immense accumulations of earth in their front.

"The Coast Ranges in several places have been subject to igneous action, which may have been brought about through heat generated from pressure exerted on the interior masses after the ice had melted away, the heat thus produced

being sufficient to cause outbursts of lava where the nature of the material favored combustion. The low plains, lakes and bays which separate the Sierras from the coast hills are in a position similar to the shallow sounds which separate Nantucket, Martha's Vineyard and Long Island from the inferior slopes of the mountains of New England. Therefore, while agreeing with glacialists who believe that great geological changes have been wrought by ice sheets in Italy and New England, it appears to me that the ancient glaciers of Sierra Nevada have accomplished far greater work, owing to the Sierras being situated in a more favorable position to receive and condense the humidity from the ocean. Hence, with a low temperature vast quantities of snow would gather on their lofty sides, and at the same time their longer range and greater declivity would cause the ice sheets to move down their steep slopes with greater force than the glaciers which passed over New England."

Astronomical.

A more than ordinary interest appears to be moving astronomers at the present time in scanning the heavens for new discoveries in stellar space, and in studying the surfaces of the bodies composing our solar system. Jupiter has been the principal center of interest for a year or two just past; but with the almost total disappearance of the "spot" which formed the chief object of interest, astronomers are looking in other directions for something new.

At a recent meeting of the Royal Astronomical Society, Mr. Raynard read a note on a narrow belt which he had seen on the planet Saturn. He said that he believed narrow belts similar to those seen upon Jupiter, were very rare. There were many observations of broad belts of a bluish-brown color upon the ball of the planet, but he was not aware of any other observation of a sharply defined narrow belt. While observing the planet on the evening of November 4th, with an 18-inch silver-on-glass reflector, he noticed a narrow, dark belt, which stretched across the disk, and at moments of good definition could be seen to fade away toward either limb; but he thought that the decrease in intensity was not as marked as in the case of similar belts upon Jupiter.

The color of the belt was a dark blue-gray, strikingly different from the reddish-brown of the belts upon Jupiter. On the 4th of November it was a striking object, nearly as easily seen as the Cassini division on the ring, though not so dark. He estimated its breadth as not double the breadth of the Cassini division, where it is seen broadest in the ansæ. The belt was again seen on the 13th of November, but was not then so conspicuous, and the definition was not as good as on the 4th.

On the 21st he saw it again, and it was also seen by Mr. Hopkins, who observed it with him. He had tried to find whether any other persons had seen it, and found that Dr. Copeland had, on the 6th of November, seen a dark belt, which he described as in about 20° south latitude, sharp toward the equator, and shading off toward the pole. He estimated its breadth at about twice that of the great division in the ring. It should be remarked that taking ten and a quarter hours as the rotation period of the planet, the opposite side of the ball would have been turned toward the earth at the time of Dr. Copeland's observation as compared with Mr. Raynard's observations of the 4th and 13th.

Perhaps the most interesting celestial event of the year is the opposition of Mars, just occurring as we write. The first physical features of the planet that come into view are the snow caps surrounding its poles. The southern pole is now inclined toward the earth, and a small telescope, say of three inches aperture, will plainly show the circular gleaming patch of snow that covers the Antarctic region of the globe of Mars. The dark ring surrounding the snow field, and sometimes called Phillip's sea, is almost equally distinct, and some of the other seas, or spots that are believed to be seas, can be seen with the same telescope. With a larger telescope more details are visible, as it would also be able to show the two tiny moons of Mars, which revolve close to the planet, so rapidly that the inner one goes through all the changes from new moon to old moon in less than a day. Another interesting thing about Mars which can now be studied is the mysterious network of so-called canals, which cover a large portion of the planet's surface, particularly in the equatorial regions. The idea that there are really canals constructed by inhabitants of the ruddy planet can be hardly entertained when it is known that they are sixty miles and more in width.

SOLIDIFIED BISULPHIDE OF CARBON.—According to M. Mercier, by mixing boiled linseed oil with 10 per cent. of protochloride of sulphur, a gelatinous mass is formed, and if a large quantity of bisulphide of carbon be simultaneously added, the whole sets into an elastic transparent jelly, very permanent in the air, and inflammable only with difficulty, although it may contain as much as 70 per cent. of bisulphide.

PROFESSOR NORDENSKJÖLD has presented a meteoric block, which he found with others in 1870 at Ovipak, on the Disco Peninsula, Greenland, to the Helsingfors University, where it has lately arrived from America, its weight being about 10,000 pounds. Nature says the block is to be kept out in the open air, as it has been discovered that these stones waste away in a room.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RED CLOUD.—Amador *Register*, Feb. 6: This quartz claim is situated at the head of Murphy's gulch, and is owned by W. Moon and others. It is idle just now, but has been worked pretty steadily during the past four months. There is a large ledge, some say 20 ft wide, between the walls; about three ft of it is of dark streak quartz, carrying considerable sulphurets, and showing freely in coarse gold. There is a quantity of ore on the dump, and the late heavy rains this week washed the ore, and made it an easy task to pick up specimens rich in free gold.

STRIKE IN THE MAMMOTH.—Toward the latter part of last week another strike of rich ore was made in the now famous Mammoth mine at Middle Bar. The work that has been prosecuted with all possible speed, has been the running of the upper tunnel, to make connection with the shaft. This tunnel now lacks nearly 150 ft of the desired point. In pushing this tunnel, a vein of "black metal," freighted with a bountiful proportion of free gold, was encountered. It is identical in character with the ore heretofore met with in other portions of the mine. What makes this discovery so significant is the fact that it is several hundred ft distant from the point where the first strike was made, and also deeper by over 100 ft. It is regarded as very probably that it is the same vein, and in this view the mine is staggered at the vastness of the golden wall, as it were, that nature has built here. The ore is estimated to be worth \$10,000 per ton, at a rough guess. A considerable quantity was taken out in the prosecution of the tunnel, but beyond this the lead was not disturbed, and will not be worked until the tunnel reaches its objective point.

JULIAN.—This mine has been at a standstill for two or three weeks, as far as the taking out of ore is concerned. Arrangements have been made to have the ore already out crushed at the Nevills' mill. There is about 10 tons of milling ore already out, and the work of taking out about as much more already in sight will be commenced to-day. The future method of working will be governed in a great measure by the result of the crushing. There is no question that the rock will pay big, but the best method of treating this class of ores is the question to be determined.

MISCELLANEOUS.—The big tunnel at Middle Bar is making headway at the rate of about eight ft per day.

Calaveras.

SOLD.—*Mountain Echo*, Feb. 2: F. Johnson & Co. recently sold their quartz mine, situated near this town, to a San Francisco party, who intends to commence working the mine as soon as convenient. Mr. Charles Smith, Supt. of the Fair Play mine, has been placed in charge of the new enterprise. The price paid for the mine has not been made public. The new stamp mill on the Morgan mine has been running about a week and works well. It crushes an average of 21 tons of ore in 24 hours.

Los Angeles.

GRAPHITE.—*Los Angeles Miner*, Feb. 2: About one month ago an important discovery was made by Samuel Carson, on his land at Tejuca, about twenty-five miles from this city. The peculiar character of the mineral attracted his attention, and upon investigation it was found to be graphite of a superior quality. Specimens were brought to town, and resulted in A. W. Potts, A. M. Reed and Wm. Osborn becoming interested in the mine, and work actually proceeded with. A tunnel is being run so as to cut the ledge, and the results so far produced are beyond the most sanguine expectations of the owners. The ledge is estimated to be forty-two ft wide, and can be traced a considerable length by the croppings. The mineral is taken out in an almost pure state, is easily worked, and is destined to be in considerable demand as soon as its merits are brought to the attention of manufacturers. Mr. Potts sent a specimen to Dallas, Texas, and an answer in reply stated that it was the best article of graphite that had ever been received at the factory there. It is the intention of the owners to send a huge specimen to Faber & Co., the great manufacturers of lead pencils, and if the article is what it is supposed to be, and is considered favorably by that firm, regular shipments will be made to them. The mine is only twelve miles from the railroad, and will, in the course of time, prove to be a great property.

Mariposa.

CRANBERRY AND RUTHERFORD MINES.—*Mariposa Gazette*, Feb. 2: The latest news from these mines, which are situated on the north side of the Main Merced river, near the old Ferguson mine, is, that under the management of S. W. Cruique, one of the owners, a large amount of fine rock has been taken from the Cranberry, and that a drift is being run through excellent ore on the seventy foot level. Two adrastra, by water-power, have been running since January 1st, with excellent results. These mines are within two miles of the Hite and Ferguson, and seem likely to rival any of the celebrated mines in that vicinity. With the exception of an early prospect shaft sunk some 30 or 40 ft, quite a number of years ago, the Cranberry is a new mine, now developing under the most favorable auspices. The vein is a true fissure, about three feet thick and the rock well diffused with sulphurets and free gold. The vein is so favorably located on the mountain side, fronting the river, that a backing of 1,500 or 2,000 ft could be obtained by means of a tunnel, run from the base of the mountain, which would probably be some two or three thousand ft in length. It also has the advantage of a water-power second to no other in the mineral region of California.

DILTZ MINE.—The recent copious rain and snow will afford Captain Diltz a most favorable opportunity for a season's wash of a vast accumulation of gold-bearing dirt and decomposed vein matter, which he had piled up at the head of his sluices ready for washing.

THE SHROEDER MINE, same as the Diltz mine, with the exception of a hydraulic system, which it has constructed upon the claim, will enjoy the harvest of a rainy season, giving wealth to its indus-

trious owner, Mr. Shroeder, which is doubly assured from a knowledge obtained from its previous workings.

THE BUENA VISTA MINE, by the O'Gorman brothers, which is a new enterprise, met with a cause of delay one day last week, by the breaking of some portion of the engine which had to be shipped from below, also with some irregularities of the pump. At last accounts, all necessary repairs had been made, and crushing of ore is vigorously going ahead again.

Mono.

BODIE.—*Free Press*, Feb. 1: The present outlook is most encouraging, notwithstanding what prejudiced outsiders have to say. It has been shown in a solid way that this district has wonderful vitality, and that it can keep to the front vigorously in spite of all efforts to cough it down. The Standard has been the backbone—as reliable a mine as there is on the continent. The sterling worth of the Bodie Con. no one in a sensible mood can doubt. The Champion has got to work again. The Bodie tunnel makes a fine showing; the Syndicate is turning out enough bullion to make a good camp elsewhere; the Goodshaw is alive again; the Mono is full of promise, and with other mines that will commence work soon, we have indications of a prosperous season in Bodie.

STANDARD CON.—Extracted and shipped to the mills 1411 tons of ore; received 2351 ounces of crude bullion, and shipped to the company \$17,035.33. Winze from north drift No. 2, 385 level, is down 46 ft; progress 8 ft. The vein here is four ft wide. There is no change to note in the appearance of the stipes.

BODIE CON.—During the week ending January 29th, 149 tons of ore were shipped to the mill and 140 tons milled. This ore was extracted from the 600 and 780 levels and 15 carloads from the 306 level. Since last report they have been cleaning out and retimbering the Burgess south drift from the west crosscut, 306 level, in order to further prospect the vein to the southward. During the week they have been making some changes in the mill by speeding the pans from 45 to 60 revolutions, changing the system of amalgamation, etc.

GOODSHAW.—During the past week they have been overhauling the machinery of the hoisting works, and will be ready to resume operations in the mine the latter part of the present week unless further delayed by the heavy snow-storm, which may prevent obtaining a supply of water for the boilers until after the weather clears off.

BODIE TUNNEL.—The mill started up Thursday afternoon of last week and is now running smoothly. Considerable delay in starting the mill was occasioned by being obliged to dig up frozen water pipes connected with the tanks and machinery of the mill, and in consequence but little work was done in the mine.

THE CHAMPION.—Superintendent White has some men making preparations for effective work, and in a few days a good force will be employed. The machinery at the hoisting works is being overhauled and everything put in good order.

BULWER CON.—The north drift, 700 level, has been run during the week seven ft; total length 548 ft.

SYNDICATE.—The mill is running steadily and making good returns, with plenty of ore for an indefinite period.

TUNNEL.—*Homer Mining Index*, Feb. 2: The tunnel in the Isabella Mayes mine, west of the Homer, has been driven 200 ft, cutting several promising veins, and Messrs. William Mayes and others are now engaged in breasting out ore from an 8-foot vein 80 feet in from the mouth of the tunnel, having the assurance of a mill in the spring of capacity equal to the supply of ore in the mine. The snow storm has somewhat retarded mining operations this week, but most of those engaged in developing their own properties have kept steadily at work. In the Mariposa-Coyote, on Copper Creek, Jordan District, the working force has been transferred from the shaft to the tunnel. We have no intelligence from the Great Sierra tunnel, Tioga District, but it is believed that the Sheepherder lode will be reached in a week or two. The final shipment for the season of May Lundy bullion was made on Tuesday last.

Plumas.

FRENCH RAVINE.—*Plumas National*, Jan. 26: A report came from Rich Bar on Wednesday that the tunnel being driven by the French Ravine Co. had broken into the ledge, and that a four-foot vein of decomposed ore had been exposed, in which free gold could be seen.

LUCKY S.—One of the National force took a trip last week to the Lucky S. mine, in Emerald district, and his glowing description of the outlook would convince almost anyone that the veritable "bonanza" had been found. The houses, sheds, dump-house, tramway, &c., &c., are in good shape, and everything is put together with a view to successfully withstand the winter storms and snows. Much work has been done for the time spent there, and evidently to the best advantage. The main point of interest, however, is in the tunnel, which a short time ago tapped the No. 2 ledge at a depth of 110 ft, the tunnel being 190 ft long. The ledge shows splendidly; at the top of the tunnel it is four ft thick and at the bottom the whole tunnel is in quartz. The hanging wall, which it shows, is smooth as a board, showing that the vein is a true one. The rock is rich, free gold showing all over the face of the tunnel, and horn prospects giving evidence that it will pay richly. Experts put it at from \$15 to \$50 per ton. Eighty tons of rock are now piled up at the dump-house, and much more will be added to it during the winter.

San Bernardino.

PROVIDENCE MINES.—*Cor. Calico Print*, Feb. 2: The Bonanza King Co. is running with wonderful regularity. So far the company have taken nothing from their dumps. The assay value of their dump at present cannot fall much short of \$500,000. Although the company keeps their business very close, I am reliably informed that the lower level (fourth) is in fine ore of the highest grade. The mill, under the Superintendency of Mr. E. Huhn, is running constantly. Mr. Huhn has shown that he is the most thorough mill-man and metallurgist of the State by the working of ores of this camp up to so high a percentage.

A RICH STRIKE has been made by R. P. Kerr on his Perseverance mine about 1500 ft north of the Bon-

anza King extension. Mr. Kerr has been rewarded by cross cutting from the bottom of his shaft (forty ft deep) with a ten foot ledge and has not yet run through it. It carries considerable ore of the same nature of the Bonanza King and is likely to be a rival of his neighbor.

NEW MINING CO.—W. B. Caldwell & Co. have purchased a half interest in six mining claims, three on the north and east of the Bonanza King, and three on the west and south of the Bonanza King. The claims all show rich mineral. Mr. Caldwell is associated with mining men of experience and capital and is an old time prospector. I understand the new company formed will be called after the famous diamond of the Queen of England, the second largest diamond in the world.

THE KOHINOOR CON. MINING CO. has already put men to work and has struck a nice body of ore. It would seem that the contact north of the Bonanza King is going to turn out a large quantity of mineral wealth. Mr. Kerr's mine, still further north, is a highly flattered prospect, and there is little or any doubt but the Kohinoor Co. will be another Bonanza King.

THE BELL MCGILLROY MINE has had some ten tons of ore run through the Bonanza King mill during the past week, the working test showing that the owners, Dwyer & Gorman, have a good mine, although I don't speak by authority, but understand that it went \$135 per ton with very little assorting by the owners.

Shasta.

QUARTZ.—*Shasta Courier*, Feb. 2: The White mine of Lower Springs is showing up finely. The ledge is three feet wide and has a shaft sixty feet deep. Last year considerable of the quartz was taken out and worked in Waugh's arastra but the pay obtained was not very satisfactory, as the rock when assayed indicated that it could be worked to a much higher per cent by more improved process. Last week Mr. White took out a ten pound chunk of quartz from the body of the ledge, which, crushed in a hand mortar, yielded \$156. Twenty tons of ore is now being taken out to be worked in Kempton's Cannon Ball mill at Salt Creek, and the result will tell what the average rock of the mine will produce.

Sierra.

CLEAN UP.—*Mountain Messenger*, Jan. 26: The Bald Mt. Extension clean up last Sunday was 104 ounces and 1½ pennyweights—55 ounces and 1½ pennyweights from the washing of 311 carloads of gravel, averaging over \$3.29 per carload, in the small dump; and 49 ounces from the large one.

Siskiyou.

INDIAN CREEK.—*Cor. Yreka Union*, Jan. 30: Our prospects at present are favorable for a good mining season. Hydraulic miners are quite elated at the fine prospects for water, as the snow at present is some eight inches in depth on a level. No doubt we have stored on Scotts mountain at present four or five feet, where we draw our supply from in late seasons. In the way of quartz mining there is but little doing. Geo. Baker, the energetic miner, is driving his tunnel to tap the extension of the Grizzly mine with favorable prospects of soon striking the same. He has at present a tunnel some 400 ft in the mountain. Bailey & Co. shut down their mill about the 15th of Dec. owing to frozen roads and snow, which made it impossible to haul the quartz from the mine to the mill. They still keep a small force of miners getting out quartz ready for the spring to open. Their ledge is looking well, with plenty of rock in sight. Hart & Brown are busy driving a tunnel on the Siskiyou mine, on French gulch, which they expect to complete about the first of April. They expect to cut the ledge at a depth of 65 feet, they having already sunk a shaft to the depth of 49 feet, with fine prospects. I think next season we will see many ledges developed in this district. Sorenson, of New York gulch, is driving tunnels preparatory to taking out rock in the spring. He has fine prospects.

Trinity.

BULLY CHOOP.—*Cor. Examiner*, Feb. 2: Bully Choop mining district, is located in Trinity county on the western slope of the mountain of that name, just west of the boundary line between Shasta and Trinity counties, and about thirty-five miles northwest of the town of Anderson, in Shasta county. A company has recently been organized, consolidating the Foster, Susie and Cumberland mines under the name of the Cumberland Consolidated, with a capital stock of \$100,000, divided into an equal number of shares. It is the intention of the company to procure all necessary machinery for working the ore in the spring. A tunnel has been run in 228 ft. near the northern end of the Cumberland mine, the inner end being 141 ft below the surface. The ledge has prospected well and has been widening the entire distance, until now it shows a face of 24 ft. The last assay made showed \$12.56 in gold and \$1.56 in silver. All the ledges in the district are situated from 5000 to 6000 ft above sea level, any of which can be drained to a depth of 800 ft by running half as much farther. The greatest drawback to the camp has been the absence of suitable machinery for successfully working the ore. There are several small water-power mills with a capacity of about a ton per day, but, owing to imperfections, only the coarsest gold is saved—all the fine gold, which forms a large percentage of the whole, and the sulphurets going to waste. Heretofore everything had to be packed in and out of the mines on the backs of mules for a distance of ten miles over a very rough trail, but a charter has been granted and a company organized to construct a wagon road from the present terminus to the mines. Work will be commenced as early in the spring as the weather will permit, and the road completed as speedily as possible.

Tuolumne.

RICH.—*Tuolumne Independent*, Feb. 1: We have heard, from reliable authority, that Kenna & Hastings have, within a few days, struck it rich near the Arnold road, on the west side of the mountain. A cool thousand in a day is not hard to take.

LAMPHEAR.—The "Lamphear" mine, supposed to be there plenty more in the same neighborhood. There is the other end of the famous "Confidence" in the Sugar Pine mining district, is fairly beating the expectations of Mr. Chute, one of the principal owners, and at present manager, in the temporary absence of Mr. Johnnie Davis. We have time only for a passing notice of this wonderful ledge—several millions hav-

ing been taken out of the old Confidence adjoining, in a chute very similar. At the point of development under present notice, the vein is 4½ feet wide; the rich pay streak is 10 inches, carrying galena, sulphurets and coarse gold thickly intermixed. The sulphurets assay \$250 per ton. In fact the entire vein is good, and is thought will average \$200 per ton. The shaft has reached a depth of 240 feet. The ore we have seen from the north drift is extremely beautiful. The new hoisting works are 80 feet long and 30 feet wide.

NEVADA.

Washoe District.

SIERRA NEVADA.—*Virginia Enterprise*, Feb. 2: The upraise from the main north drift on the 2900 will reach the 2700 level in about 10 days. This connection will so change the draft and give such a circulation of air as will permit of the prospecting of several streaks of ore known to exist in the mine to the northward. On the 3100 level the northeast drift is being advanced as rapidly as possible. The drift has passed over the ore streak reported last week, but the face is again in streaks of quartz of the same character. There are other ore streaks passed through in the joint Union Con. crosscut that are liable to be cut by this drift to the northeast. Some of the streaks are rich in gold.

ALTA.—There has been some delay of the work in the main east drift on the 2150 level, on account of it becoming necessary to make some repairs to the shaft, between the 1750 and the 1950 level.

SAVAGE.—The work of extending the main drift northward from the south line, on the 2600 level, has been resumed. This drift will be advanced into new and wholly unexplored ground. The joint crosscuts on the Hale and Norcross line—though extended but a short distance east and west—showing good quartz streaks going north into the Savage ground.

BEST AND BELCHER.—The ground in the bottom of the joint Gould and Curry winze below the 2500 level is still very soft, and requires close watching and close timbering.

MEXICAN.—General repairs are being made in all the levels from the 2500 down to the 3100, and when the connection in the Union Con. is made—which will be within three weeks—and a good supply of air obtained prospecting will be commenced at several points, both on the 2900 and 3100 levels.

COMBINATION SHAFT.—The new hydraulic pump, the air compressor, and all the other machinery, is now doing excellent work. Sinking for the 3000 level has been resumed, and the shaft will be pushed down to that point without delay.

HALE AND NORCROSS.—Good progress is being made in the sinking of the winze below the 2800 level. As soon as it has attained a depth suitable for a sump, a station will be opened and prospecting commenced at the 2800 level.

GOULD AND CURRY.—The joint Best and Belcher winze below the 2300 level is in soft ground that requires close timbering.

ORISKANY.—On the 150 level they are still extracting a considerable amount of ore, and besides are doing a great deal of prospecting.

CROWN POINT.—As the late storm will undoubtedly result in a good stage of water in the Carson river, allowing the mills to run up to their full capacity, we shall soon see a full force of men engaged in the extraction of ore from the mine.

UTAH.—On the 1750 level the northeast drift is making rapid progress in quartz that is beginning to give very promising assays.

UNION CON.—The connection will be made between the main north and south drifts on the 3100 level within three weeks.

YELLOW JACKET.—They will now doubtless soon be able to put on a full force of men, as the late storm can hardly fail of bringing the water in the Carson river up to a good milling stage.

CON. VIRGINIA.—The joint California winze below the 2700 level is being sunk and timbered at the rate of from 10 to 15 ft per week. It will reach the 2900 level in about 10 days.

CALIFORNIA.—On the 1700 level the joint Con. Virginia winze is making the usual progress in fair working ground. It will reach the 2900 level in about 10 days.

Bullion District.

THE MINES.—*Battle Mountain Messenger*, Jan. 30: The Lady of the Lake mine never looked better, and Mr. Robertson, the Supt., is endeavoring to have the company start up the works with a full force of men, but it seems that Messrs. Frisbie & Radovich do not see the necessity of this step. There are no less than 100 tons of first-class ore on the dump, and thousands in sight in the mine, of the richest ore that has ever been seen in the camp; yet it does not seem to me that the proper process to reduce the ore has been adopted. The same is also true of the ore from a majority of the mines in this district. Messrs. Blossom and Dunn, the owners of the Lady Don, are lying back awaiting further developments in other contiguous properties, knowing that the ledge from which so much good ore has been extracted and where the quantities are now in sight, is the extension of their ledge. The Leopard, the Lady of the Lake western extension, was jumped, but the Ross brothers, of Beowawe, who own it, repaired to the ground, and proving that it was not jumpable, regained possession of it. Paul and McKittrick have struck it rich, and have brought in some of the richest ore yet found in the district.

Hot Springs District.

WOODRUFF.—*Cor. Esmeralda Herald*, Feb. 2: I promised you a few items on my arrival at this place—Hot Springs mining district—but found the place so quiet, I thought it best to look around and take items before writing to you. We have a pony mail which arrives and departs to and from this place once a week. This district is in a basin or desert, surrounded on all sides by high mountain ranges. On the flat or desert is to be found acres upon acres of fine soda and borax ground. Several claims or locations have been taken up in borax and soda and also salt, and dotted here and there with monuments of location. I can also add that many acres still remain unlocated, as good as yet found for borax as well as soda. Water can be found at a depth of from fifteen to twenty-five ft, by sinking

anywhere along the flat. The basin is about twelve miles in length, by eight miles in width. Very little is being done at present by the owners of the salt, soda and borax locations, beyond keeping up the assessment work. The Great Eastern mine, owned and worked by Nick Perceval, is a fine piece of property, showing several tons of high grade ore on the dump, and hundreds of tons could be extracted from the tunnels, drifts and stopes. This mine is well opened and cannot fail to bring in time, a stake to its owner. The Eagle series of mines, number One, Two and Three, are three distinct parallel ledges, and are situated on Antelope mountain. These mines are also well developed and have had a great deal of work done in them in tunnels, drifts, stopes and shafts, exposing to view large bodies of good ore. A Woodruff has four men at the Eagle number One, taking out ore. He has run a drift south, thirty ft on the ledge from the bottom of the main shaft, showing a solid vein of quartz eighteen inches in width, assaying from \$50 to \$120 in gold, and \$2 to \$5 per ton in silver. The ledge is encased in white porphyry. True foot and hanging walls three ft apart. They have now about twenty-five tons of good milling ore on the dump, and are taking out a ton to the mill on each shift. Eagle number One and Three are principally gold, while number Two is mostly silver, averaging \$30 to \$60 per ton.

Columbus District.

THE COLUMBUS CON.—*Time Pressure*, Feb. 3: The main shaft has attained a depth of 75 feet below the station of the third level. The bottom of the shaft is now in vein matter, some of which gives fair assays. The drift from the shaft, on the third level, was extended about 8 feet during the week, making a total length of about 48 feet. The rock in this drift still continues to be very hard, although it has lately changed somewhat in character. The drift from the bottom of the Bonanza winze, running to connect with the shaft on the third level, has been extended 6 feet, making a total length of about 95 feet. The face of the same still continues in broken up vein matter that yields fair assays at times. The crosscut running south from the lateral drift on the 150 foot level has attained a length of about 95 feet. Since the date of the last report there has been no material change in the rock encountered in extending this crosscut. The appearance on the first level remains about the same as when last reported.

Highland District.

IN THE FRONT.—*Pioche Record*, Feb. 2: Highland is steadily coming to the front. While some men working in the upper level of the Mendha mine were engaged in running a crosscut they run into the old ledge, which had been lost for years. Long ago there was a drift run 300 feet for the purpose of finding this ledge, but it was never found. There are now employed a force of men in this mine nearly equal to that at the Day. The usual quantity of ore is being taken and shipped to the furnace daily. Prospecting work is being carried on at the old Hamburg, and day and night shifts are being worked. On Wednesday the men engaged in running a crosscut in the opposite direction from the ore recently struck, encountered a vein of fine appearing ore.

Patterson District.

THE PATTERSON STRIKE.—*Eureka Sentinel*, Feb. 2: Arthur Matheson, who arrived last night from Hamilton, says that he visited Patterson District a few days ago, and was disappointed in finding the ore strike recently made there not as big as at first represented. Yet, for all this, it is a good paying prospect. The ledge, which is quartz with rich chloride all through it, is six feet thick, and it has been stripped for a distance of 20 feet, paying more than wages all the way. From a chunk containing about four cubic feet of ore he took what he thought was a good, average sample, determined not to be fooled by selecting the best. The sample assayed \$94. Some of the rock assays from \$1,200 to \$1,500. The ledge dips at an angle of about 30 degrees, having a hanging wall of clay shale. There is another ledge about 75 feet distant which dips toward it, and may prove to be an offshoot from the main body. No greater depth than six feet has been attained. Very little snow has fallen in that locality this winter, so the ledge will be prospected only on or near the surface, until a rich chute is encountered, which it will be thought advisable to sink on. At present the mine is paying small dividends, with which the owners are well satisfied.

Pinto District.

FUTURE PROSPECTS.—*Cor. Eureka Sentinel*, Jan. 30: This, like a great many mining camps in Nevada, has suffered considerably from lack of enterprise and misrepresentation. Silverado is the most favorable looking country for mineral I have seen in Nevada. There are several good mines here which by systematic work, economical and judicious management, would yield a magnificent interest on capital. The Queen mine, owned by the Jones Bros., is a splendid property, but the owners are poor men and have not the means to develop it. The Silverado mine is also a fine property, but it requires capital to develop it. The Maryland, Silver Nugget, Fairplay and several other mines in the district, could be made good paying properties by the liberal investment of capital. The formation seems to be granulated and fossiliferous lime, shale and quartzite, with occasional fragments of the metamorphic and volcanic rocks. The character of the ore is chloride, bromide, Stedefeldite, copper, silver glance, argenteriferous galena and oxide of lead. There is no work being done on any of the mines for wages. There are a number of men prospecting, and some are gathering a good many shells. The weather, with the exception of a few cold days, has been delightful for the past month, but from present indications we are going to have it rough, and that pretty soon.

Safford District.

TUNNELS.—*Cor. Eureka Sentinel*, Jan. 30: The Onondaga tunnel is being run on contract by Howes & Doherty, and nothing will be done until connection is made with the shaft. The Zanola tunnel has nearly reached the bottom of the shaft. They think a few hours more will finish the work, when they will probably commence taking out ore from the lowest point of the development. Dan and Tom Shields are taking out some high grade ore from a claim called the General Shields, formerly the Franklin. Several tons are already sacked, which, they feel confident, will pay to ship to Salt Lake. Their mine adjoins the Illinois.

Sherman District.

AN OPEN FIELD.—*Nevada State Journal*, Feb. 2: The discovery of what is believed to be valuable mines in Sherman district, on what is to all appearance a continuation of the Comstock lode, has called to mind the fact that years ago rich ore was found in the mountains north of the Truckee river, between Reno and Wadsworth, and there are several old timers in Reno who are familiar with the locality who will go there as soon as the weather will permit and try, if possible, to spy out the place where the famous lode crosses the Truckee. It would not be at all strange that within the next few years bullion producing mines should be found all along that range of mountains from Virginia City to Pyramid Lake.

MAGENTA MINE.—*Glass Valley Union*, Feb. 1: Seven small loads of rock taken from the Magenta shaft have been cleaned up this week and gave a return of \$21 per load without including sulphurates. Rock is now being taken out of the prospect shafts on the croppings at seven different points, and shafts Nos. 2 and 3 are turning out rich rock, which it is expected will yield fully up to a previous crushing which went to \$120 per load. The big head of water which was struck on the 400 level a week ago is now under control and the water pumped out to the bottom of the shaft. An eight inch pump has been fitted up to be put in the shaft to avoid any detention from a similar cause in the future. In addition to this a hoisting engine is to be set up to raise the quartz, as it is the intention to put to work a larger force of men to extract quartz from the levels and stopes that are now opened in the mine.

SITU' DOWN.—Work was suspended at the Idaho mine yesterday owing to a break in the South Yuba Canal, which supplies the water power for running the hoisting and milling machinery of the mine. Repairs will be completed to-day and regular operations are expected to be resumed to-night. As the pumping is done by steam power no inconvenience will be occasioned by the break as to this part of the machinery.

ARIZONA.

NOTES.—*Prescott Courier*, Feb. 1: Chloriders are shipping rich ore to Benson, from Humburg district. Jim Lane's mine, near the Tiger, is yielding ore which pays to ship. The Black Warrior is in good condition. Superintendent Eaman says he has a great deal of fresh ground in which to stope, so that sinking is not necessary. The Peck people have their men drifting towards the Occident. Silver Belt continues to send down ore to Benson. Turkey creek miners are taking out ore. B. T. Riggs, who has worked in mines for thirty years, has just looked at the Kimball and Gold Block mines on Lynx creek, eight miles east of Prescott, and thinks well of them. Mr. Clark, on Groom creek, is working his mines and running his small reduction works. We hear that everything is satisfactory over there. An expert has been examining Charley Rush's mine and likes it. J. C. Herndon showed him the property. Mr. Tracy and other placer miners tell us that they have water in abundance for sluicing. The Dosoris company lately made another large shipment of choice ore to Pueblo. The experts who are coming from New York to look at C. C. Bean's copper fields, are expected here some day this week. It is not likely that the Howell company will do much until spring. United Verde company are still struggling with the transportation question. It is hard for them to get bullion in and coke out.

GOLD MINES.—*Prescott Courier*, Feb. 1: Mines now being worked by G. W. Curtis and others, near Lynx creek, eight miles east of Prescott, are the Kimball and Gold Block. The former is pierced by shaft to a depth of 150 ft. The vein is 4½ ft wide; the walls are perfect. We have seen a great deal of rock from this mine. It is gold bearing. Mr. Curtis will be pleased to exhibit about 300 tons of it. Indeed we have his word to the effect that there are, on the dump, four hundred tons of it. The rock is certainly very rich, free gold is everywhere to be seen, and we judge the ledge to be worth a fortune. The Gold Block is about four ft wide. It, too, has the reputation of being rich. A good wagon road runs by these mines and the trip from Prescott is easily and comfortably made by wagon. Mr. Curtis and partners are negotiating for a mill to work their ores. They are, meantime, sinking, drifting and enlarging the dump piles. Were these mines in some desert spot, near the S. P. railroad, they would cause a regular Quijotoa excitement. Here, but little is said concerning them, although they are almost within rifle shot of Prescott.

COLORADO.

GENERAL NOTES.—*Colorado Miner*, Jan. 26: Since our last statement the Bismarck has continued to show up mineral, and considerable was shipped from the mine during the past week. Conway & Co. brought down several tons of good ore from the Little Emma during the week. It ran in one class over 500 ounces to the ton. The Corry City continues to look up and a large quantity of ore, some of it milling over 200 ounces, is being taken from the development workings alone. The new machinery was started up last week. Henry Mears & Co. have started in to work the Lucky, the Lucky Extension, Emma, Hidden Treasure and Silver Quartz lodes, a group of claims on the north slope of Democrat mountain, whose surface workings already show up well. We are informed that the Moline Tunnel company will resume work in their tunnel about the first of next month. Blais and Morrison are working four men on the Albany lode on Fall river. The Albany is as yet only a prospect, the shaft being down only 35 ft. There is some ore in it, however, and the owners think very highly of the claim. The same parties are working eight men on the Grand View lode, on Republican mountain, which continues to improve steadily. A large quantity of ore is being taken out, and during the week a trail has graded to the mine, so that transportation can be made easy.

MARION.—The Marion, or Sherman mountain, almost on the line of the Seven-Thirty wagon road, is now being worked by H. E. and G. W. Hollenback and Ed. M. Clemans, who are both sinking and drifting. They have a small body of ore in sight.

ALABAMA.—The Alabama is one of the Equator group of mines, and is worked through the main Equator tunnel. About 600 ft from the mouth of the tunnel a drift has been run both east and west

on the Alabama vein. On the east this drift extends 350 ft, and about 150 ft back from the breast is a 100-

SONORA.—Egan, Conway & Co., who are working the Sonora, a few days since encountered a large body of quartz, with scattered mineral, in the lower drift, which is now in about 270 ft. The extent and value of the find cannot yet be determined.

foot stope, which has now been raised about 75 ft. Dean & Co. opened up a few days since the streak of ore, probably five inches wide, about which there has been so much talk. The ore is decomposed galena and gray copper and is very rich.

VICE-PRESIDENT.—Six men are at work on the Vice-President. In the breast of the drift, which is now in 300 ft, some ore is exposed. Though not much in quantity, it is of excellent quality, and the lessee is going to stay with it. In the stope on the same level, but some distance from the breast, they are at work on a large body of 80 ounce ore.

IDAHO.

BEARING THE COLOR D'ALENE.—*Cor. Salt Lake Tribune*: Our estimable deputy sheriff, Mr. Ed. F. Winn, of Oneida county, was called north by a telegram from your section of the country, on official business. In Mr. Winn's trip north he gave a close objective eye to the new excitement in the Color d'Alene, and as his views of such matters are considered sound by all that know him, I herewith take pleasure in giving them publicity. Mr. Winn's visit to the capital of the Color d'Alene, Eagle City, was very transitory, and of course he formed his ideas rapidly and gives expression to them deliberately. Mr. Winn is one of those gentlemen who look upon such affairs as the Color d'Alene, from purely a business, or rather commercial, standpoint and sees everything from his position void of excitement, consequently his views command a very large consideration. Without the conventional form of a regular interview, I will give you his observations. He left the Northern Pacific Railroad at Trout Creek Station, and for a distance of 26 miles traveled on foot over a narrow trail—a kind of towpath—to Eagle City. Upon arriving at Eagle City he found the town was built of three-fourths tents, the remainder being log cabins. A population of some 400 persons occupy these tenements. The miners showed him some nice coarse gold; saw one nugget that was reputed to weigh 572. All the gold is on bed rock; saw gold quartz reputed to have been found in the district as good as any he ever saw; cannot tell the extent of the country for placers. The miners are very reticent in their answers to queries, causing a suspicion that there is a "screw loose." A survey is being made from Heron Siding to the mines for a railroad track. There is a rumor of a shorter route by the way of Belnap, further south. Everybody going in seems to be prepossessed in favor of the saloon or restaurant business. "The fact is that the whole thing is one of the biggest sells that was ever gotten up, or it is a big thing." Though I am satisfied that he discovers now opened up do not justify the tremendous excitement that seems to pervade the country. Now, sir, taking Mr. Winn's dispassionate view of this Color d'Alene country, while on his transient and official business, I cannot see the animus of the craze that seems to have seized to whole mining world. There has never yet been given a report from that country that justifies the rush that is reported to be going there, and until something more than two or three holes sunk on Pritchard creek is developed up, I think the excited minds of our mining community should simmer down. From the time reports—excitable, inflammatory—that the country has received, there is really created a fastidious excitement that should from logical points be discontinued.

THE NEW MINES.—We gather the following items about the Color d'Alene from various sources. **EDITORS PRESS.** The Northern Pacific has made arrangements to take out 1,800 miners from the Gunnison country, Col., to the Color d'Alene mines. These are in addition to the 2,000 Black Hill miners, for whom arrangements were made several days ago. A great many nuggets worth from \$10 to \$50 each have been found in the Color d'Alene mines. A large number of miners are congregating in Salt Lake from Silver Reef and other districts, intending to outfit here for the Color d'Alene country. They will take their own teams and provisions enough to last them six months. Pritchard creek (Color d'Alene Mountains) carries a large, swift-flowing body of water, sufficient for all mining purposes, if claims should be located its entire length. The gulch is heavily timbered, many of the trees being from 12 to 14 ft in circumference. It costs about \$4 a day to live in Eagle City. There are five ft of snow on an average at Eagle City. The Ives, Campbell, Davis and Widow claims are being worked and paying from \$16 to \$25 per day. A party of 15 miners from Montana on their way to Eagle City, got wrecked on the Color d'Alene, and lost everything they had. There is quite a scarcity of flour and bacon at Eagle City. Flour raised in five days to \$16 a barrel and bacon 65 cents. Beef is 50 cents and venison 25 cents. In regard to the new mines, the Truckee Republican, of Wednesday, gives some recent information. T. Rogers, an old resident of that section, has just returned from the new gold fields. He is very enthusiastic in regard to them, and thinks that a new Leadville or Virginia City will soon grow up in its midst, as it is believed that the mining discoveries will extend over a region 100 miles in extent. Ed. Dyer, a former Truckeeite, writes from Spokane City, and says parties are fitting out there daily, and the sales of goods to mines foot up into the thousands every 24 hours. It is thought that a city of 40,000 inhabitants will grow up in the mines during the present year.

MONTANA.

BUTTE.—*Cor. Salt Lake Tribune*: The mines of this district commence the new year under very favorable auspices. The Anaconda, Parrot, Lexington, Alice, Moulton, Colusa, Clark's Colusa, Clark's Original, and the Silver Bow Co.'s mines all start the year 1884 with full forces of men. The Anaconda, however, can hardly be said to be working a full force. This property when the reduction works shall go into operation, will give employment to a much greater number of men than at present employed. Whatever stopping is being done now is confined mainly to the higher grade ore, which is shipped to Liverpool. None of the medium and lower grades

are being extracted, except what is unavoidable in mining the best quality. The low grade is being piled at the mine, and has now reached the enormous quantity of fully 200,000 tons. This huge pile—a mine on the surface—will be sent to the company's reduction works for treatment when connected with the mine by railroad, which will be in early spring. This company is shipping 2,000 tons per month over the Northern Pacific at rates below those formerly paid. Competing railroads and reduced freight charges are doing and will continue to do a great good to the mining interest of this Territory. The metallic wealth of Montana is enormous, and cannot be estimated. The output will continue to increase for an indefinite period. What the territory lacks most is some of the old-fashioned California enterprise, or the Colorado enterprise of to-day. There is no State or territory in the Union that contains as many metallic veins as this does, nor more that has been so lightly touched and run over. But things are gradually changing, and Montana will in the near future lead the list in metallic wealth. Butte, if nothing develops itself to put a check upon her, will this year far outstrip the record of the year just closed. The Liquidator and Gagnon companies are both sinking one hundred ft each. During the prosecution of this new development stopping is temporarily suspended, and will not be resumed until the new levels are opened. Both of these properties rank with the best. The Lexington company is also sinking the main shaft. It is the intention of the managers to sink 300 ft additional to the present depth—300 ft—which will make an aggregate depth of 800 ft, before cross-cutting the new, then to run two cross-cuts 150 ft apart. The vein disclosed in the last cross-cut—500 ft level—is large and rich, associated with the usual refractory metals, which have hitherto been successfully reduced by the gentlemen in charge, and the magnificent mill and other appliances erected for the purpose. The ore reserves in this mine at the present rate of extraction, are calculated to furnish the 60-stamp mill for a period of two years. The additional 300 ft now being sunk will double this period.

NEW MEXICO.

KINGSTON.—*Cor. La Vegas Gazette*, Feb. 2: This camp has to-day a better prospect of success than any other camp in New Mexico. Twenty thousand dollars has been taken from the "Solitaire" mine at an expenditure of \$500. The "Bullion" mine was bought for \$10,000. Up to date over \$75,000 has been taken out of it, the work, etc., costing \$36,000, and this year as much more can be expected with good reason. The "Superior" cost \$20,000, and they have taken out \$70,000, but they could have taken out much more, for they have passed bodies of ore that they have not touched, their work being only that of prospecting, and they have actually taken out and shipped "obstructions" so to speak. In sinking their shaft and running their drifts to explore the mine, they have met and taken out the ore upon which they realized the above mentioned \$70,000. The "Iron King" company are so well satisfied with their property that they are now putting up a \$60,000 smelter to reduce their ore. I could go on and name a dozen mines with hundreds of tons of ore on the dumps, but the above is enough to give you an idea of why we expect so much from Kingston. The formation is the best there is to make a rich and deep mining district. There are a series of contacts between lime (primary) and porphyry, with here and there large quartzite "blow-outs," and I am told on the very best authority, a well known mining man, that they are mines in Old Mexico exactly similar to the "Superior" and "Bullion" that have been worked to the depth of 2,000 ft, the ore becoming richer as depth was reached. The Superior has already a 300 level.

OREGON.

RAIN.—*Jacksonville Times*, Feb. 2: Much more rain has fallen in Josephine county than here and most of the miners are busily at work. The rain that fell during the week was not generally heavy, hence did not afford the miners everywhere an abundance of water. N. Cook informs us that the miners of Willow Springs precinct have not been able to do much as yet, which is generally the case throughout Jackson county. John Hall of Pickett creek is managing Bybee & Co.'s diggings near Waldo and left for that destination Wednesday morning. He says they are in better shape than ever and that the prospects for a good cleanup are favorable.

UTAH.

THE FRISCO M. & S. CO.'S SMELTERS.—*Southern Utah Miner*, Jan. 30: It having been reported that the Frisco M. & S. Co. intended building a new and extensive smelter at Franklin, south of the city, inquiry was made at the company's office to ascertain further particulars. The matter is under consideration, but no definite arrangements have yet been made. The mines of the company in Beaver county are yielding large quantities of ore; enough, in fact, to keep a number of stacks constantly running, and as smelting can be conducted near Salt Lake to greater advantage than in Southern Utah, the smelter will doubtless be built this spring. Fuel is cheaper here, and all necessary fluxes are at hand. The works will be on a very extensive scale, and will be quite an acquisition to the country.

THE F. M. & S. CO.—*Southern Utah Times*, Feb. 2: Friday night the miners and employees at the Carbonate Concentrator and Rattler mine were all discharged and the Frisco Mining and Smelting Company's operations in Frisco closed for an indefinite period. In reply to an inquiry regarding the closure, one party who knows, said "That it was on the account of the lack of sand on the part of the management," he admitted that the mine had never much more than paid expenses, but thought that in view of the recent opening out of new ore bodies in the Rattler mine, the company showed poor judgment in closing down. One by one are the props being pulled from Frisco's underpinning. "It is rumored that the Cave mine, property of the Frisco M. & S. Co. has also been indefinitely shut down, and the company's action is believed by many to be the result of disunion. It is hoped that matters will soon be readjusted and work resumed.

For Mining Shareholder's Directory, Stock Reports etc., see page 113.

Bodie's Bullion Record in 1883.

When the MINING AND SCIENTIFIC PRESS published its annual review of mining on this coast for the year past the record for Bodie district had not been made up. The Bodie Free Press, which has always kept an accurate record of the product of the mines of that district, has an excellent and carefully prepared article on the subject, which we here reproduce:

During 1883 there were less mines being worked and less producing bullion than in any year since 1877. The Noonday mill of 40 stamps, the Spaulding mill of 10 stamps, and the Miners' mill of 4 stamps, were closed down throughout the year. The Bodie Tunnel mill of 15 stamps was closed down the last 6 months of the year, and the Syndicate mill of 20 stamps the first 3 months. The Standard has kept 50 stamps employed constantly and the Bodie Con. 10 stamps. John Wagner's tailings mill was employed about 6 months. Considering this idleness upon the part of so many of our mines and mills, it will be a surprise to the majority of our readers to know that the bullion shipments in 1883 reached the large sum of \$1,582,667.08.

There has been such a marked improvement in the mining outlook of the district, commencing with the 1st of January, owing to the valuable strikes in the Standard and Bodie, that we confidently predict a doubling of the amount during the present year. Not only will the mines mentioned, and more especially the Bodie, largely increase their own production, but we expect to see every stamp in the district employed before the year is out. Already the Bodie Tunnel mill has resumed work (which, however, it would have done in any event), with prospects which are certainly most encouraging. The Syndicate has now a better grade of ore than ever before, and it will run steadily throughout the year. The Goodshaw, Champion and Dudley will soon be in operation, and negotiations are in progress looking to the resumption of operations on the Belvidere and South Bulwer. It would be strange if, with the fine bodies of ore which are known to exist in the Noonday, North Noonday and Red Cloud mines, and the fact that they are now in such a condition that they can be started up out of debt and with a clean balance sheet, they should not be consolidated and worked under heter auspices than before, and upon a self-sustaining basis.

The Standard.

The Standard Con. has crushed, during 1883, about 70,000 tons of ore, from which the sum of \$1,153,181 83 has been produced, an average of about \$16 50 per ton. The grade of ore has been lower than in previous years, and a greater quantity has been put through the batteries. In the earlier history of the district, when the average grade of Standard rock was about \$60 per ton, it would have been thought impossible to declare dividends upon ore of the grade which is now considered good. Necessarily a much greater quantity must be handled, and there is a consequent increase in expenses. Fortunately for the stockholders there are vast quantities of ore in the mine of this grade, and the able and experienced local management of the company understand precisely how to work it for dividends. During 1883 the Standard Company disbursed twelve regular monthly dividends and one extra dividend of \$25,000 each among its shareholders, aggregating \$325,000. The total amount of dividends declared by the Standard Company up to Dec. 31, 1883, aggregates \$4,350,000, a larger amount than has ever been declared by any mining company on the Pacific coast, not on the Comstock, excepting one—the Eureka Consolidated, which has disbursed dividends to the extent of \$4,817,500. Possibly we should also exclude the Richmond Consolidated, of the same district, an English corporation, of which we have no record. The dividend record of the Raymond & Ely was \$3,075,000, while that of the Northern Belle has aggregated but \$1,260,000. The best feature of the Standard is the fact that it gives assurance of a long continued season of productive-ness.

The following tables give the production of the Standard Con. mine by months during 1883, and the total production of the mine to Dec. 31, 1883:

OUTPUT OF STANDARD CON. MINE IN 1883.			
	Gold.	Silver.	Total.
January.....	\$85,409 03	\$13,954 52	\$99,405 55
February.....	107,347 28	14,466 10	121,813 38
March.....	75,590 10	9,311 52	85,219 62
April.....	97,939 10	14,996 16	112,735 26
May.....	95,984 38	12,651 36	111,656 34
June.....	98,416 02	13,956 95	112,372 98

November.....	62,388 11	8,678 50	71,066 61
December.....	61,757 38	7,713 14	69,500 52
Total.....	\$1,015,357 04	\$139,824 79	\$1,155,181 83

THE BODIE.
Throughout the year of 1883 the Bodie Company's mill has been running steadily upon an inferior grade of ore to that which it has heretofore worked. The mill is of but ten-stamps capacity, and it is situated at such a distance from the mine that it requires a high grade of

ore to pay expenses. In 1882 about 5,500 tons were crushed, netting in the neighborhood of \$90 per ton. During 1883 a larger quantity has been worked, aggregating probably 6,500 tons, and averaging about \$38 per ton. While this shows a considerable falling off in quality, it was still of a grade not to be despised, the Standard Company having paid dividends upon rock of less than half the value, but in large quantities. No dividends were paid by the Bodie Company in 1883. In previous years dividends have been paid to the extent of \$1,295,000. With the recent discoveries the Bodie is destined to enter upon a new career of prosperity. The following tables give the production for the past year, and the total production of the Bodie mine to date:

BULLION SHIPMENTS OF THE BODIE CON. MINING COMPANY FOR THE YEAR ENDING DECEMBER 31, 1883.			
	Gold.	Silver.	Total.
January.....	\$10,980 43	\$15,088 42	\$26,077 85
February.....	9,577 62	16,712 53	26,290 15
March.....	7,754 69	13,705 69	21,460 38
April.....	9,092 86	15,395 04	25,087 90
May.....	13,277 51	18,902 44	32,179 95
June.....	7,996 53	10,188 60	18,185 02
July.....	5,330 49	7,117 68	12,448 17
August.....	4,755 48	7,535 95	12,290 73
September.....	6,670 26	8,983 83	15,654 09
October.....	8,649 46	7,931 33	16,581 29
November.....	10,121 90	9,284 05	19,405 95
December.....	10,359 68	10,792 93	21,152 61
Total.....	\$105,176 32	\$141,643 78	\$246,820 10

Legal rate, \$1.2229 per ounce.
TOTAL OUTPUT OF BODIE CON. MINE TO DECEMBER 31, 1883.

	Gold.	Silver.	Total.
1878.....	\$1,042,236 80	\$188,200 00	\$1,230,436 80
1879.....	764,067 12	128,333 00	892,400 12
1880.....	429,817 80	75,000 00	504,817 80
1881.....	363,105 14	63,000 00	426,105 14
Total.....	\$3,599,226 86	\$644,533 00	\$4,243,760 86

The Syndicate.

The Syndicate mill of twenty stamps, has been running since about the 1st of April. The ore is low grade, but it has been worked at a minimum of expense. There has been a great improvement in the quality of ore of late, and with a further slight improvement the company would be able to pay dividends. The following tables give the bullion shipments by months and the total shipment of the mine to date:

BULLION OUTPUT OF SYNDICATE MINE IN 1883.			
	Gold.	Silver.	Total.
April.....	\$10,140 77	\$715 49	\$10,856 26

1881.....	134,760 30	20,000 00	154,760 30
1882.....	75,458 20	10,000 00	85,458 20
Total.....	\$323,314 43	\$216,000 00	\$539,314 43

The Bodie Tunnel.

The Bodie Tunnel mill ran a portion of the time only in the early part of 1883. Since the mill closed down the work of exploration has been in progress, and a large amount of good ore has been uncovered. The mill is an excellent one, and has all the modern improvements. It is situated, like the Syndicate, directly under the mouth of the tunnel, and it is capable of reducing ore from their own mine or the Beehive Con. at very light expense. The following tables give the production during 1883, and in previous years:

OUTPUT OF BODIE TUNNEL MINE IN 1883.			
	Gold.	Silver.	Total.
January.....	\$9,643 00	\$0 00	\$9,643 00
February.....	10,434 00	\$0 00	\$10,434 00
March.....	12,241 00	\$0 00	\$12,241 00
April.....	8,408 00	\$0 00	\$8,408 00
Total.....	\$40,726 00	\$0 00	\$40,726 00

OUTPUT OF THE BODIE TUNNEL MINE TO DECEMBER 31, 1883.			
	Gold.	Silver.	Total.
1881.....	\$10,623 81	\$0 00	\$10,623 81
1882.....	129,216 53	\$0 00	\$129,216 53
Total.....	\$139,840 34	\$0 00	\$139,840 34

Total Production of Bodie District in 1883.			
	Gold.	Silver.	Total.
Standard Con.....	\$1,155,181 83	\$139,824 79	\$1,295,006 62
Bodie Con.....	246,820 10	\$0 00	\$246,820 10
Syndicate.....	92,390 96	\$6,752 14	\$99,143 10

Total Product of Bodie District.

The total product of Bodie District to December 31, 1883, has been as follows:

	Gold.	Silver.	Total.
1877.....	\$797,022 80	\$80,000 00	\$877,022 80
1878.....	2,129,732 58	\$183,000 00	\$2,312,732 58
1879.....	2,556,847 58	\$3,000 00	\$2,559,847 58
1880.....	3,063,690 13	\$20,000 00	\$3,083,690 13
1881.....	3,172,749 71	\$0 00	\$3,172,749 71
Total.....	\$15,520,499 12	\$216,000 00	\$15,736,499 12

THE PRODUCTION OF EACH MINE.
The total production of the various Bodie mines since the commencement of operation here in 1877 has been as follows:

	Gold.	Silver.	Total.
Standard Con., 1877-83.....	\$9,662,212 58	\$1,155,181 83	\$10,817,400 41
Bodie Con., 1878-83.....	246,820 10	\$0 00	\$246,820 10
Noonday and North Noonday, 1879-82.....	1,623,280 50	\$0 00	\$1,623,280 50
Bulwer Con., 1879-80.....	358,592 71	\$0 00	\$358,592 71
Syndicate, 1879-83.....	339,250 48	\$6,752 14	\$346,002 62
Bodie Tunnel, 1878-79.....	208,130 07	\$0 00	\$208,130 07
Bodie Tunnel, 1881-83.....	129,216 53	\$0 00	\$129,216 53
Belvidere, 1880.....	25,991 23	\$0 00	\$25,991 23
Oro, 1881.....	14,155 66	\$0 00	\$14,155 66
Red Cloud Con., 1877-78.....	10,927 50	\$0 00	\$10,927 50
Concordia, 1881.....	5,070 38	\$0 00	\$5,070 38
Sitting Bull, 1879.....	3,495 60	\$0 00	\$3,495 60
Mexican, 1877.....	2,000 00	\$0 00	\$2,000 00
Dudley, 1880.....	1,746 05	\$0 00	\$1,746 05
Summit (Kate Rogers), 1877.....	1,500 00	\$0 00	\$1,500 00
Boston Con., 1882.....	1,331 00	\$0 00	\$1,331 00
Miscellaneous, including placer gold, shipments by banks, tailings mill, etc., 77-83.....	336,741 06	\$0 00	\$336,741 06
Total.....	\$15,520,499 12	\$216,000 00	\$15,736,499 12

The Dividend Record.

Of the above production of over fifteen and one-half millions of dollars, the following

amounts have been disbursed as dividends by the companies named:

Standard Con.....	\$4,350,000
Bodie Con.....	1,295,000
Bulwer Con.....	165,000
Total.....	\$5,810,000

Of the foregoing amount \$35,000 was disbursed by the Bulwer Company in 1883.

We submit that this is a very creditable record, and gives the lie to the oft-repeated statement that mining does not pay, and that Bodie is "played out."

The Miners' Association Circular.

OFFICE MINERS' ASSOCIATION,
SAN FRANCISCO, Feb. 1, 1884.
SIR:—The Miners' Association deems it due to its members, as well as to all persons interested in mining in the State of California, to call their attention to the effect of the recent decree of Judge Sawyer in the suit of *Woodruff vs. The North Bloomfield Gravel M. Co., et al.*, a copy of which is enclosed. It is sweeping and harsh in all ways, and until modified or reversed by a higher Court, is the law of the State.

As will be seen by a perusal of the decree, the defendants are not only prohibited from mining, but from selling or disposing of water for any kind of mining, either quartz, drift, placer or hydraulic.

It must be evident to all that it is not the amount of debris which is discharged from a mine into any stream, but it is the right to discharge any debris of any kind which is enjoined. It is not a question of quantity or kind—as gold mining cannot be carried on without water or without debris or tailings or muddy water—it must be evident that mining cannot be carried forward on the Yuba or Feather Rivers, or their tributaries, and for same reasons cannot be carried on upon any other stream or water course in the State. For any person who may be a riparian owner upon any watercourse below any mine, which in any way deposits any debris in the stream or any of its branches, or muddies its waters, can enjoin the mine owner from so doing, it matters not what kind of a mine it is or where it is situated. If this is the law, as laid down by Judge Sawyer, it will apply to all, and it will not do for any one engaged in mining in California to hug himself with the delusion that the law will not apply to him or his mine.

This association has often called the attention of the quartz drift and other miners to the danger to their interests, under the belief, now a certainty, that in the attack upon the hydraulic miners all mines would be involved. The result, so far as Judge Sawyer is concerned, has proven that the surmises of the association were correct.

The counsel of the association are of the opinion that the decree of Judge Sawyer can be either modified or reversed in the U. S. Supreme Court on appeal.

To appeal the case will involve a large outlay, as the testimony alone covers over 12,000 pages, and the few who have borne the large expense of this and other suits in which the right to mine at all has been, as is now apparent, involved, desire from the members of the association their views as to whether or not an appeal shall be taken.

The Association also wish from others, than members, an expression as to whether or not they will aid in the expense of an appeal to the Supreme Court at Washington. To this end, the Association request you will examine carefully the decree (a copy of which is enclosed), and then that you fill up and return to it the enclosed blank, which speaks for itself.

If the response from the miners throughout the State will justify this Association, it will appeal the Woodruff case, and carry it through to the end, and so settle the question in suit. If not, it will let those who are specially interested in the case do as they please, and, as an Association, take no further part in the litigation.

It may be well, however, to say that a combined effort upon the part of the miners is now most important, for no one alone can stand the expense, and as the Association is the only channel or organization through which this effort can effectively be made, it should receive the unanimous support of all classes of miners, by liberal contribution, without regard to the kind or class of mine—for the time has now arrived when it is not a question of the kind or degree of mining—but of the right to mine at all.

Your early and prompt attention is earnestly called for. It may be well to state here that there is no individual or personal interest to be subserved by the Association. Its counsel is among the most prominent of the profession, with seven years' experience in this sort of litigation, and its officers are probably more familiar with the subject matter at issue than any other persons.

It is worse than folly for any mine owner, in the face of this decree, to say that his property and rights are not in great danger; and unless the miners as a class are satisfied to abandon their property without a struggle they should now stand shoulder to shoulder, and sustain the association to the end—as it says to you plainly that unless Sawyer's unjust decree can be modified or reversed on appeal, your mining property is valueless.

The Board of Counsel of the Miners' Association, as at present composed, consists of L. L. Robinson, Egbert Judson, Henry Pichoir, E. J. LeBreton, Thomas Bell and Robt. McMurray, representing mines on the San Juan Ridge; J. H. Bolles, of Excelsior mine of Smartsville;

Orrin Gowell, of Nevada City; Jas. L. Gould, of Dutch Flat, and A. Hayward, Thos. Price and J. B. Haggin, representing the mining interest at large.

Prompt action is not only desirable, but necessary. L. L. ROBINSON, President.
W. A. SKIDMORE, Secretary.

To the Miners' Association, 320 Sansome street, Room 23:—The undersigned hereby makes application to become (or continue) a member of the Association, and incloses \$10 as initiation fee (provided initiation fee has not already been paid).

The undersigned, for himself, or the Company represented by him, believes that the case of *Woodruff vs. N. Bloomfield et al.*, should be appealed to the Supreme Court of the United States for reversal or modification, and to this end agrees to pay monthly, for the term of — years, the sum of — to the Miners' Association, for that object.

New Bridge on the Trinity River.

Mr. E. M. Benjamin furnishes to the Trinity Journal the following description of the wire suspension bridge across the Trinity river, at Junction City. The bridge is the property of Dr. Albert H. Hayes, of Boston, Mass., and has been constructed for the purpose of conveying the water of Canon creek to his gravel mines on the opposite side of the river. A brief description will suffice to show the magnitude of the enterprise, and it is all that I can give you at present.

The Towers.

The work was commenced on the 16th day of August, 1882, by cutting for the northeast tower foundation, running the tunnels for the anchorage, and excavating through the tailings in the river bed for the foundation of the southwest tower. Difficulties were encountered in sinking this tower, as the bed-rock was much lower than the water in the river. We were obliged to construct coffer-dams, and employ a steam engine to pump out the water while we sunk to the bed-rock and laid the stone masonry to high water mark. The foundation to the tower is 2x25 feet at the base, with a starling projection up the river of six feet, all laid in Portland cement. This pier is strengthened by the insertion of 300 iron anchors, some of which pass through from side to side. The top of the tower is forty-six feet above the highest water ever known in Trinity river, leaving the floor beams of the bridge twenty feet above high water mark. This will allow the river to fill up (as it will to some extent) with tailings from the mines above, and yet leave a large margin for safety, during the fifty years which it is estimated will be required to "work out" the Doctor's mines.

The tunnels for the anchorage on the northeast side of the river, are run forty feet into the bed-rock, on an incline of 14° 55'. Near the back of these tunnels are planted the four-inch anchor bolts thirty inches deep in the bed-rock, with back stays or guys anchored to two and a half inch bolts, set two feet into the bed-rock, and all set with sulphur.

The anchorage for the tower on the southwest side of the river is planted twenty-three feet deep in the tailings, and walled in with heavy masonry, laid in hydraulic cement.

The Cables.

Are 4½ inches in diameter, 516 feet long, and each composed of 1,050 No. 11 American gauge Bessemer steel wires, the breaking weight of which is about 2,800 pounds to the strand. The tension strain on each cable when the bridge is loaded with 3,000 miner's inches of water passing over it will be 320,000 pounds, and the weight on the towers 82,500 pounds to each cable. The cables are served with No. 11 Norway wire, ¾ inch pitch. Six hundred pounds of white lead and 130 gallons of linseed oil were consumed in the construction of the two cables (not laid on with a brush, but poured in from a cup as the cable was served), so that all the vacancies between the wire are filled with paint.

Weight of the Cables.

There was used in the cables 43,524 pounds of wire, exclusive of the weight of the white lead and oil. The cone blocks, links and pins, anchor-plates and bolts, tower-bolts and saddles, suspension-rods, clips and washers weighed 39,102 pounds.

The bridge is now complete, with the exception of enclosing the towers, and Mr. Guthrie is engaged in getting out the timber for that purpose. There is 32,000 feet of lumber in the framework of the towers.

The Hydraulic Pipe.

Which is to convey the water across the Butler divide in the mountain is 34 inches in diameter, and 2,212 feet long, the greatest depression being 310 feet.

The pipe through which the water will be conveyed across to the McKenna mine is 18 inches in diameter, and will be used under any desired pressure of from 200 to 500 feet. About one-half of the pipe is already made.

The pipe for conveying the water to the celebrated Keno mine will be 5,067 feet long and 27 inches in diameter. We expect to have the iron rolled for this pipe in time to arrive here about the 1st of July, 1884. The span between the towers of the bridge is 350 feet.

THE ENGINEER.

Cantilever System of Bridge Building.

The completion of the new cantilever bridge over the Niagara Falls for the Michigan Central railroad has brought the new system into prominence, and is likely to awaken considerable interest wherever bridging high points is desirable.

The engineer of the Central Bridge Company of Buffalo was asked to explain the peculiar character of what is now referred to as a cantilever bridge. The new Niagara bridge is the first bridge of that style and affords an excellent illustration of the principle. The term cantilever is borrowed from a bracket or double bracket supported in the center as used in architecture, and here the architectural engineer and the mechanical engineer unite labors. The principle is here first applied to a bridge proper; but in constructing the road bed for the West Shore, Hudson River railroad, essentially the same principle was applied where the bracket rested upon an abutment with one end inserted into masonry under the rock of the mountain, and the arm projected out over the water, upon which the track is laid.

In the cantilever bridge there are two arms of the bracket, one extending over the river, the other toward the shore and secured to masonry. Upon the two arms reaching toward each other from each shore, a central span is laid, or the bridge proper is so laid connecting with each but having the usual preparations for responding to the changes in temperature.

The shore arm of the cantilever or bracket rests, as I have said, upon a second pier, built back of the first one at the river's brink. If there was no such support, any weight—like that of a railroad train—if placed upon the shore arm, would depress it toward the ground and correspondingly elevate the outer or stream end. It would be as if, after perfectly balancing a plank on a log, you should place a weight at one end of the plank. But this is not enough. Suppose the railroad train has passed under the tower over the main pier out upon the cantilever or balanced beam; the extra weight would depress the outer end and at the same time elevate the inner or shore end. So the shore end not only rests upon a support of masonry, but it is fastened to it, to prevent the train from tipping the beam up into the air and falling into the stream.

For bridges having long spans the system is asserted to be the most economical. Less material need be used to secure the same strength, rigidity and stiffness than in a suspension bridge, for instance. Less false work or scaffolding is needed for the erection of a cantilever bridge than for any other braced structure, thereby making it capable of construction with more ease and less danger of disaster and with no obstruction to navigation. The central span resting upon the outer or stream ends of the two brackets can freely expand with the heat of summer and contract with the cold weather. One end of this central span is fastened to one of the brackets, the other end being placed upon rollers. The deflection from the horizontal under the full load capacity of the bridge is not half so great as it would be in a suspension bridge of the same length of span.

The principle is by no means new, only as in its application in the erection of so extensive structures. Supporting structures by two long arms upon uprights is an old idea, but capable of numberless modifications in a live engineer's management, as may be seen in the single post supports of the New York elevated railways. The new Niagara river bridge, however, is the first bridge of any magnitude actually built upon this system. The first one in Europe will be the great bridge across the Firth of Forth, Scotland, now building. The cantilever system, as will readily be suggested to any engineer, is capable of a great variety of additions and modifications. The arms may be thrown out from one central pier instead of from two near shore, and a roadway may be elevated above the railway track, or one may be suspended below the track, or both if such were desirable, or the truss or bracket may be reversed and built entirely above the pier so as to be a low bridge and still offer no obstruction to the high water.

A FEAT IN MINING ENGINEERING.—The Pottsville Journal says: At East Franklin colliery, on Thursday, was consummated one of the greatest feats in mining engineering that has been accomplished in the coal regions, and it is a signal instance of the power of mathematical calculations, as applied to the construction of works of this kind. The Reading Coal and Iron Company contracted with a party from the oil regions about nine months ago to put an eight-inch hole down at this colliery, but on account of the inefficiency of the workmen it did not succeed. A few months ago the company contracted with Mr. McEehoue, of Scranton, to continue the work. As the hole is to be the passage way for a cable, and is 760 feet in depth, some fears were entertained by Mr. George Patterson, resident engineer, that the mines would not be pierced just where it was intended they should be; but when the drills struck bottom they were not a half inch out of the way of their calculations.

USEFUL INFORMATION

What the Colors of Buoys Mean.

"On entering any harbor in the world," said a pilot to a *Sun* reporter, "where the channel is marked by buoys, you will find that those on your right as you pass in are painted red, and those on your left black. If you should see one painted in red and black horizontal bands, the ship should run as close to it as possible, because that indicates the center of a narrow channel. Buoys with red and black vertical stripes always mark the ends of spits and the outer and inner ends of extensive reefs, where there is a channel on each side. When red and black checkers are painted on a buoy it marks either a rock in the open sea or an obstruction in the harbor of small extent with a channel all around. If there are two such obstructions and a channel between them, the buoy on the right of you will have red and white checkers, and the one on your left will have black and white checkers. When a wreck obstructs the channel a green buoy will be placed on the sea side of the wreck, with the word 'wreck' plainly painted on it in white letters, provided there is a clear channel around it; otherwise, an even number will be painted in white above the word 'wreck' when the buoy is on the right side of the channel, and an odd number if the buoy is on the left."

COLORING SOFT SOLDER YELLOW.—When brass is soldered with soft solder, the difference in color is so marked as to direct attention to the spot mended. The following method of coloring soft solder is given by the *Metalworker*: First, prepare a saturated solution of sulphate of copper (bluestone) in water, and apply some of this on the end of a stick to the solder. On touching it with a steel or iron wire it becomes coppered, and by repeating the experiment the deposit of copper may be made thicker and darker. To give the solder a yellow color, mix one part of a saturated solution of sulphate of zinc with two of sulphate of copper, apply this to the coppered spot and rub it with a zinc rod. The color can be still further improved by applying gilt powder and polishing. On gold jewelry or colored gold, the solder is first coppered as above, then a thin coat of gum or isinglass solution is applied and bronze powder dusted over it, which can be polished after the gum is dry and made very smooth and brilliant; or the article may be electroplated with gold, and then it will all have the same color. On silverware the coppered spots of solder are rubbed with silvering powder, or polished with the brush and then carefully scratched with the scratch brush, then finally polished.

PAINTING ON ZINC.—According to the *Painters Magazine*, painting on zinc is made easier by employing a mordant composed of one quart of chloride of copper, one of nitrate of copper, and one of sal ammonia, dissolved in 64 parts of water, and to this mixture is added one part of commercial hydrochloric acid. This is brushed over the plate of zinc, and after 12 or 24 hours it dries a dullish gray color. Painting upon this surface the colors will adhere in a perfect manner. Another method, according to the same authority, is as follows: Procure some muriatic acid of full strength, and drop into it some pieces of zinc until effervescence ceases. Add an equal quantity of water, and with a sponge tied to a stick wash over every part of the surface to be painted. This roughens the surface and takes off that sort of greasiness which prevents paint from adhering. After the acid has remained a short time wash it over with water or diluted vinegar, dry off and paint.

THE "silkworm gut" used for fastening fish-hooks to fishing lines is taken from the silkworm just as he is ready to open. The worm is very carefully pulled apart and the glutinous matter from which the worm spins its silk, and which is contained in the *serotaria*, or silk glands, is then drawn out in a single thread of variable length, from one and a half to three feet, and is slowly allowed to dry. Spun says, regarding the production of this material, that "hitherto silkworms only have been employed for this purpose, but a plan has been set on foot to utilize caterpillars which infest food plants. It is to be hoped that it will prove a practical success, as, if the gut can be produced in long pieces, and at a moderate price, it will find numerous applications."

VIOLIN VARNISH.—The *Scientific American* gives the following formula for preparing a beautiful varnish for violins: Rectified alcohol, half gallon; add six ounces gum sandarac, three ounces gum mastic, and half pint turpentine varnish; put the above in a tin can by the stove, frequently shaking until well dissolved. Strain and keep for use. If you find it harder than you wish, thin with more turpentine varnish.

DRAFTING WATER THIRTY-SEVEN FEET.—Mr. David P. Stewart, of Buffalo, it is said has shown to the *American Machinist* a method of lifting water thirty-seven feet by a common suction pump. About twenty-five feet from the bottom of the suction pipe there is a tee with an ell, from which latter there is a vertical capped pipe extending up to the height of the suction valve. The lower end of the suction

pipe has a check valve. Both pipes are filled with water, and the vertical side pipe, or stand pipe, capped. The pump will suck the water out of the stand pipe and form in it a vacuum that will sustain the water in the suction pipe, and enable water to be drafted thirty seven feet. If so, the same principle ought to apply to even greater lifts.

COOKING BY ELECTRICITY.—Some parties in Canada are reported to have invented a machine for cooking by electricity. It consists of a saucepan or hot plate, so isolated by non conductors that the bottom forms the positive pole of a current. The other pole is attached to a movable point which travels over the under surface of the pan in circles sufficiently quick not to burn a hole through. Some cakes were cooked in the apparatus and eaten by the inventor and his family, who are believed to be the first members of the human race who have eaten food cooked by the electric spark. One lady declared she tasted the flavor of electricity "quite strong."

THE BANANA TREE AS A FOOD PRODUCER.—The Spaniards have a superstitious reverence for the banana, believing it to be the fruit of which Eve partook in Paradise. It is asserted that 44,000 pounds of bananas can be produced on the soil that would be required for 1,000 pounds of potatoes, and that the area that would be required to raise wheat enough for one man would produce bananas enough to feed 70 men.

ARTIFICIAL CORK.—A patent has been granted to Grunzweig and Hartman, in Ludwigshafen-on-the-Rhine, covering a process of making artificial cork by thoroughly incorporating sixty-three parts of ground or powdered cork chips with 180 parts of boiling starch paste. The resulting plastic mass is pressed into forms and then dried in hot rooms.

TO DETECT FALSE BUTTER.—An Austrian chemist gives this recipe for detecting false butter: Melt a little of the suspected article; soak a wick in it. When again solid, light it like a candle; blow it out. If it smells of blown-out candle, it is oleomargarine; if of fresh butter, why, butter it is.

FREIGHT CURIOSITIES.—A Boston paper says that one of the curiosities of railroad freights is that earloads of good potatoes can be laid down in that city from sections of the West at ten cents per bushel lower than potatoes can be brought from Maine, one of its nearest neighbors.

GOOD HEALTH.

Dandruff and Loss of Hair.

Dandruff is a condition in which branny scales are shed from the scalp in great abundance. It may be due to eczema or pityriasis, or may result from a disorder of the sebaceous glands, and from aene. The latter is the most common cause of the disease. In this form of affection, the abnormal secretion of the fat glands appears upon the scalp as yellowish scales. This condition is sometimes present upon the nose and cheeks as well as the scalp. It is often a very annoying complaint. When affecting the scalp, it sooner or later results in loss of the hair. This is not because the dandruff destroys the hair, but because the same disease which causes the dandruff interferes with the nutrition of the hair, thus occasioning its loss. On account of its tendency to produce baldness, the disease should never be neglected. Dandruff is most generally occasioned by disorder of the digestion, or some other debilitating disease.

Treatment.—Restore the general health by proper attention to the digestion and hygiene. For dandruff of the face, apply the same remedies recommended for the skin. The scalp should be treated in the same way, by gentle shampooing with ordinary washing soap, once or twice a week. A very soft brush should be used. Neither a stiff brush nor a fine comb should ever be used for removing dandruff. For shampooing, a liniment composed of equal parts of castor-oil and alcohol may be rubbed on the scalp, or an ointment composed of a dram of tannin to an ounce of vaseline.—*Good Health*.

Health in the Shop.

It is profitable for proprietors to make their shops and factories healthy and pleasant for their workmen. This topic is ably discussed by the *Industrial World*:

Some of the best things to be seen at the modern shops are the conveniences for the personal cleanliness and comfort of the men employed, and from the few thus equipped the most useful lessons may be learned by those still content to run in the rut of unfortunate indifference which has so long prevailed.

The placing of such things as water-closets in the centre or at one side of a large shop apartment is a step in the right direction, not only in making sure that the enclosure will be kept in the best possible condition; but also that there shall be the least possible time lost in it. Both of these considerations have a real money value, and the better chance of thus maintaining the sharpest watch over them both while attending to other current duties, relieves foremen or

managers from some needless sources of annoyance.

It was long ago proposed to use for washing fixtures in machine-shops, and other places where they must be provided, along pipe of suitable size with a small thumb pet-cock on the under side of it for each man, but this very convenient arrangement has been by far too rarely used. A sink or trough of moderate size is needed to catch and lead away the water falling from the hands, and the whole is found to be of the most reasonable cost in furnishing and in the amount of water consumed. Of the ease with which such a water supply could be heated in the supply-pipe itself, and of the importance that each man should have clean water for his own use, mention need hardly be made.

It has but seldom been found by those who keep close watch of the effect of such improvements that they do not pay handsomely for themselves. Their influence is by no means so indirect or so uncertain as has sometimes been supposed.

WOOD IN SURGERY.—Wood is employed scientifically in surgery in a different form from ordinary splints. A foreigner has introduced wood-wood as a cheap and useful dressing for wounds, and it is being prepared extensively as a commercial staple for surgical dressings. It is finely ground wood, such as is extensively used in the manufacture of paper. It is a clean looking, delicate-fibered, soft, yellowish-white substance, having an odor of fresh wood, and absorbs an immense quantity of liquid. The best wood-wood was found to be that which was obtained from the *Pinus picea*. The wood-wood thus procured was first pressed, passed through a sieve, then dried and impregnated with a solution containing $\frac{1}{2}$ per cent of sublimate and 10 per cent of glycerine. The advantages claimed for this dressing are numerous. It is cleanly, fresh, and of a whitish color; it is at the same time soft and delicate in texture as cotton, and "extraordinarily cheap." The actual price is, however, not stated. It possesses some antiseptic properties naturally, has an agreeable odor, and is exceedingly elastic even in thin layers, so that bandages can be put on more lightly with this than with any other dressing. Its absorbent properties are so high that it takes up 12 times its own weight of water, so that 10 ounces of well dried wood-wood after complete saturation attain a weight of 120 ounces.

GERMAN TREATMENT OF DIPHTHERIA.—The new German remedy for diphtheria—turpentine—appears to find many advocates. Children take one teaspoonful morning and evening, adults a tablespoonful; in children, tepid milk is given after it, and it might also be mixed with the same. Half an hour after the administration of the drug, a bright redness begins to spread from the margin of the diphtheritic exudation, and this redness becomes generally diffused over and takes the place of the false membrane, and the disease is said to disappear within twenty-four hours without leaving the slightest trace. While this remarkable effect is said to be invariably met with when the remedy is made use of at the very commencement of the disease, those who recommend it so highly assert that it is also successful, only less rapidly, in cases that have progressed for several days.

HOT WATER FOR TORPID LIVERS.—Two Polish physicians have been making experiments for the purpose of ascertaining the effects upon the liver of alkaline mineral waters. Their results indicate that alkaline waters increase the quantity of bile when taken freely. These experiments also included observations upon the effects of hot water upon the liver, the conclusion being that hot water possesses the same properties as alkaline waters. We have proved in a large number of cases that the use of hot water is one of the most effective means of encouraging a torpid liver. When the liver is torpid, there is usually a red sediment in the urine. From six to eight glasses of hot water should be taken daily until the sediment disappears.

A SUBSTITUTE FOR TRANSFUSION OF BLOOD.—William T. Bull, M. D., Surgeon of the Chambers Street and New York Hospitals, says the use of saline injections in Asiatic cholera in the early part of this century demonstrated the safety of such a procedure, and likewise its inefficiency in checking the career of that disease. Within a few years, however, this method has risen to the level of a life-saving measure, as a substitute for the transfusion of blood in conditions of acute anemia and collapse. Of nineteen patients who have been subjected to the operation, when at the point of death, thirteen have entirely recovered; in three death was averted, but occurred later; and in the remainder only a temporary improvement was effected.

FETID AND PROFUSE PERSPIRATION.—This condition is most commonly found in the feet, although the armpits and other parts of the body are sometimes affected. The following treatment will be found successful in most cases: Just before retiring at night, take a hot and cold foot-bath, dipping the feet first in cold water then in hot, allowing them to remain in each for about one half minute, and repeating the operation fifteen or twenty times. Then wipe with a soft towel, and, when nearly dry, rub with subnitrate of bismuth, using a large teaspoonful of the powder for each foot.

Passing Events.

Snow in San Francisco is something new for
us to record, yet it fell here on Wednesday
night and Thursday morning. The bright sun-
shine that followed soon dispelled it, but the
hills around the bay were clothed in white for
several hours, much to the passing delight of
the San Franciscans, to whom the sight is un-
usual.

As the days lengthen there seems to be more
and more interest displayed in all that concerns
the Cœur d'Alene mines. Miners all over the
country seem to be getting ready to go there,
and many are on the way already. Still all
accounts agree that it is altogether too early to
attempt to do anything in that cold region for
two or three months to come. It is specially
hazardous for men without means to attempt
the journey, on the hardships of which all
agree.

MECHANICS' INSTITUTE LECTURES.—The usual
winter course of lectures under the auspices of
the Mechanics' Institute commenced this week.
Prof. Joseph Le Conte gave the first lecture on
"Mountain Building," a subject which will be
continued on the 14th. Alexander Del Mar,
"Corporations," February 21st; Major W. A.
Jones, United States Army, "Home Illumina-
tion—Lamps," February 28th; Walter M. Le-
man, "The Drama of the Stage," March 6th;
A. Wendel Jackson, "Crystals," March 13th;
and Prof. W. B. Rising, "Explosives," March
20th and 27th. Tickets may be had at the
Library. Admission will be free.

Mining Investments.

The statement is very frequently made that
mining is not profitable, and that it costs a dol-
lar to get a dollar out. Even when that is the
case, the old dollar is not lost, but has simply
changed hands, while there is also a new dollar
for somebody else. It is a story of blades of
grass in dollars. There is a new dollar added
to the world's circulating medium and riches;
and one which is not perishable either, in the
ordinary sense of the word, though with most
of us the dollars disappear more rapidly than is
readily accounted for. Even when a man puts
\$25,000 into a mine and only \$5,000 comes out,
the world is \$5,000 better off, though the indi-
vidual may have \$20,000 less in the bank than
he had. But that \$20,000 has been scattered
among miners, teamsters, traders, storekeepers,
etc., and done a great deal more good than
when stored away in a bank.

But it is pretty certain that the eighty or
ninety millions of dollars in gold and silver
turned out every year by the mines of this
coast do not cost even half of that sum for
actual production. If that has been the case,
California, at any rate, has not had its share of
the invested millions, though it gave back \$15,
000,000 in hard coin. Other regions have had
scant investments, yet have given returns. It is
very difficult, indeed, to get at exact figures of
investment and returns. Yet all these new mil-
lions must enrich some, and increase the comfort
and happiness of many more. Thousands are
given employment directly by the mines, and
many other thousands are benefited incidentally.
Yet there are people, because a sort of gambling
has been more or less identified with the min-
ing interests, who deery mining in every way,
and try to discourage it. There is no industry
of a nature which will yield a direct sum of
ninety millions a year which should not be en-
couraged in every way.

Wages in Borax Mining.

The manufacturers of borax on the Pacific
coast labor under several disadvantages as com-
pared with producers elsewhere. Labor and
other factors of production are dear; the borate
fields are located in desert regions which afford
few facilities for carrying on the business of re-
fining, being at the same time several hundred
miles distant from San Francisco, the principal
entrepot and shipping point for the entire coun-
try. After shipment to San Francisco, the
borax has to make long journeys by sea or land
to reach the great marts of the world.

The following statement of expenditures,
made by one of our largest California borax
mining companies, on account of labor and sup-
plies for a month, fairly represents expenditures
of the other borax companies, both in California
and Nevada on account of these items.

Scale of Wages for White Labor in Borax Mining and Manufacture.

Classes of Employees	Wages
	Per day Per month
Clerk at mine	4.25 130.00
Agent at railroad station	100.00
Blacksmith, first	\$5.00
Blacksmith, helper	3.00
Engineer	4.00
Teamster	1.00
Swampers or helpers	1.00
Feed Teamster	3.25
Coppers	3.25
Boiler men	4.25
Washmen	1.25
Laborers	1.25
Cook	50.00

In addition to this the men are boarded free,
which costs the company about \$1 per day each.
These are wages for white men.

The wages of Chinese are different. The
same company pay Chinese firemen \$50 per
month, and the laborers \$1.25 per day; these
men boarding themselves.

The white labor list for a month, with 31
days, equals 25 men \$1,504.96; and 35 Chi-
nese comes to \$1,400, or a total for labor for a
month of \$2,904.96.

Forage consumed for the same month
amounted to \$620.61 for two large teams of
four animals, which is 50 cents per day per
animal of the ten transportation teams which
have 55 miles of wagon haul. There were also 35
animals for teams at the works, which cost
\$224.47 for forage during the month.

Average Wages Per Month in Borax Min- ing in Nevada

Classes of Employees	Rate
White laborers	45 and 50 cents per day, equal to \$75
Chinese	40 and 45 cents per day, equal to \$60
Superintendents	60 to \$75 and found
Teamsters	50 to \$60 and found
Blacksmiths	75 and found
Medicines	75 and found
Engineers	100 and found
Firemen	50 and found
Transmitters	75 and found

Volumetric Determination of Mercury.

There recently appeared in one of the German
metallurgical periodicals a description of a new
method for the volumetric determination of
mercury, which we translate and condense. If
recently precipitated mercurous chloride is
covered by sulphuretted hydrogen water, the
mercurous chloride is at once transformed into
sulphide and hydrochloric acid. If the excess
of hydrogen sulphide is removed in a suitable
manner and the quantity of chlorine in the so-
lution determined, the proportion of mercury
may be readily calculated. The author pro-
ceeds in the analysis as follows: If the mercury
is present in the mercurous state, it is precipi-
tated at once with the sodium chloride. If it
exists in the mercuric state, and no hydro-
chloric acid is present, a sufficiency of sodium
chloride is added, and then a solution of ferrous
sulphate and excess of potass.

The mixture is allowed to stand for a few
minutes in the cold and diligently stirred up
with a glass rod. The precipitate of mer-
curous oxide and ferrous-feric oxide is strongly
acidified with dilute sulphuric acid and stirred
till the black precipitate has become a pure
white, the formation of mercurous chloride
being complete. This is filtered and washed
well, placed along with the filter in a beaker,
covered with sulphuretted hydrogen water and
allowed to stand for a few minutes. The hydro-
chloric acid formed is neutralized by the addi-
tion of an excess of elutriated barium-carbonate,
whilst the excess of sulphuretted hydrogen is
removed by a solution of zinc acetate, which at
the last is added in drops until no more odor
of hydrogen sulphide is perceptible.

The precipitate is filtered again, and, after
washing, the filtrate is mixed with an excess of
potassium chromate and titrated with a silver
solution in such a manner that at first a small
excess of silver is run in, which is removed by
means of a measured quantity of an equivalent
solution of sodium-chloride, and the operation
finally completed with a centinormal silver
solution.

Proportion of Profit to Yield.

On page 106 of this number of the MINING
AND SCIENTIFIC PRESS are some very interesting
statistics concerning one of the most prominent
mining regions of California—Bodie, in Mono
county. The recent revival in that camp makes
them of more than passing interest. We more
particularly call attention to them, however, as
they afford a very strong argument in favor of
the statement that "mining does pay," and
just at this time are useful in proving the value
of an industry which many see nothing in.

These mines have been producing for some
seven years, and their record in production and
dividends is as follows:

Year	Bullion	Dividends
1877	\$1,250,000.00	\$200,000.00
1878	1,150,000.00	135,000.00
1879	2,300,000.00	80,000.00
1880	1,000,000.00	1,000,000.00
1881	1,100,000.00	35,000.00
1882	1,100,000.00	80,000.00
1883	1,100,000.00	35,000.00
Total	\$11,250,000.00	\$5,114,000.00

Out of a net product of fifteen and a half
millions, dividends to the amount of nearly six
millions have been paid. And this is not a sin-
gle exceptional mine, but the result of seven
years' work in a big mining camp. If all the
manufacturing establishments could make any-
thing like that proportion of profit, business
would be better than it is. Of course there
have been failures and individual losses, but
there have also been successes and individual
profits. The general result shows in favor of
the latter. The proportion of profit to yield is
what we want to call attention to in this in-
stance. What it cost to cause the product or
yield we do not know, nor is it of moment in
this connection. The result is probably double
what any legitimate manufacturing establish-
ment would expect in the ordinary course of
business. This money is out of the ground itself
—a product of nature—and is not the result of
barter or commercial exchange.

**PLATINIZED MAGNESIUM AS A REDUCING
AGENT.**—Pure water is not decomposed by
magnesium, but if a trace of platinum chloride
be added, the decomposition takes place freely.
A writer in *Berg und Hüttenmanische Zeitung*,
recommends this as a very useful reducing agent
for organic substances.

A DYER cannon ball crusher has been sent to
Micaal City Camp, Washington county, Idaho.

Foundry Notes.

At the Golden State and Miners' Iron Works
they are making an upright engine 14x14 for
the Judson Manufacturing Company's works
across the bay. They are also making a 12x18
engine for the California Iron and Steel Com-
pany at Clipper Gap, to be used as a hoisting
engine.

This foundry has a gang of men at work on
the Von Schmidt dredger in the Brooklyn Basin,
Oakland harbor, where it has been some six
months dredging out the approach to the pro-
posed canal into San Leandro bay. Heavier
shaiting and gears are being put in, and the ma-
chine is being generally overhauled.

The dredger has done so much more work
than was expected of it that its parts were
found in many places to be too light. It has
been doing some very heavy work, digging from
4,000 to 6,000 cubic yards a day, where the old
clam-shell could dig but 1,000. The owners
have a large contract, and will be able to do
even better work when the various parts are
strengthened.

The foundry are now working castings for
120 new logging cars being built by Carter
Bros. for the California Redwood Company, who
are going to use them in the timber region of
Humboldt county. This company has lately
bought out John Kentfield, and is going exten-
sively into lumber manufacture. The works
have just completed a hydraulic press for this
company, which is intended for pressing car
wheels or axles.

Mining Revival in Shasta.

As will have been seen by those who have
read our weekly summary of mining news, there
is quite a revival of mining in Shasta county.
For a long time that section of the State has
been somewhat neglected by the mining capital-
ists, and the miners have had to get on as best
they could. In fact, the miners have been
working out their own salvation without much
outside help. It is gratifying to note now,
therefore, that mining matters in Shasta are
looking up, and that many promising claims
are coming into public notice. These success-
ful mines will help others, as they will encour-
age many men to go on with their own claims
and develop them to good paying properties.
In conversation recently with Judge Aaron Bell,
he told us of the Iron mine (silver) owned by
Camden, McGee and Sallee, and which is seven
miles northeasterly from Shasta, and three
miles from the line of the California and Oregon
branch of the C. P. R. R. The ledge is said
to be something like 150 feet wide. They are
shipping ore to San Francisco and Colorado,
and it sells as high as \$140 per ton. Shasta
county is looking up in every direction. The
silver mines are promising, and the gold mines
also. There have been about half a dozen of
the Dyer cannon ball quartz mills (built by the
Globe Iron Works of the city), put up, and
they turn out well. Some 500 new settlers
have come into the county in the past six
months. In the coming season there will be
80 miles of finished railroad.

Bluestone.

The origin of the bluestone industry at Day-
ton, Nevada, which subsequently attained such
magnitude, was due to the endeavors of cer-
tain mill owners who found it necessary to re-
fine, in order to profitably dispose of the bul-
lion which they obtained in working Comstock
tailings. By the base process, as the one in
vogue was termed, it was found advisable to
employ large quantities of copper sulphate in
amalgamating, and even as much as 20 pounds
to a ton of tailings were used. In consequence,
the bullion produced contained from 80 to 90
per cent of base metal, principally copper.
Besides the loss in copper the mill owner was
obliged to bear a heavy discount on his
produce.

The estimated amount of bluestone (sulphate
of copper), manufactured in this country in
1882, was between 9,000 and 10,000 barrels of
an average weight of 350 pounds. The spot
value was about 54 cents per pound, making
the total value of the product between \$150,
000 and \$200,000. The principal centers of
manufacture are: Omaha, Neb.; Cleveland,
Ohio; Philadelphia, Penn.; Salem and Boston,
Mass.; New York City; Newark, N. J.; Provi-
dence, R. I.; Baltimore, Md.; Dayton, Nev.,
and San Francisco. The leading utilizations of
bluestone are in pan amalgamation, the manu-
facture of Paris green and dyes, and in tele-
graphy.

A New Pulley.

The Fulton steel pulley is a new article of manufacture, combining strength and lightness to an unusual degree. Reference to Fig. 1 of the engraving will give the reader an excellent idea of the appearance of the pulley. It will be seen to consist of three parts—the rim, the center and the hub. The rim and center are of steel, while the hub is malleable iron. One great feature of the Fulton pulley lies in the corrugations of the steel center, or disc. Every machinist will at once recognize the immense additional strength imparted to the pulley by these corrugations. They may be laid on concentrically, as in the cut, or radially, to meet the wishes of users. The corrugating of these discs is done by a powerful press made especially for the purpose. The sheet of hot steel is placed in the press, and the die brought down with great force, not only corrugating the disc, but punching out every alternate "ear," by which the rim is afterwards to be made fast. The withdrawal of the die pulls up the other alternate ears, thus by one operation leaving the center fully corrugated, and the ears bent alternately to one side and the other, ready for finishing. The rim, as before stated, is of steel. This rim is drawn around the center disc while cold by powerful machinery, and there riveted to the ears. The place of meeting of the two ends of the rim is a double joint, and as strong as any other point in the periphery of the pulley.

The hub is cast in two halves, one for each side of the wheel; the face of each half being cast with a corrugation to fit snugly to that of the steel disc. The two halves of the hub are placed in position and bolted firmly together through the disc. A sectional view of the pulley is shown at fig. 2, and fully illustrates the method of joining the various parts. This cut also shows the form of the corrugations on the steel disc, with the alternate ears on either side riveted to the rim. The rivet holes are punched and the riveting completed while the pulley is in the chuck, so that when it is released the pulley is made. Fig. 2 also shows the hub with its corrugations closely hugging the disc, held there by the bolts. A split pulley is also made under the Fulton patents, which is so cheaply done as to bring the price down nearly to that of the ordinary pulley. The Fulton pulley can be made up to five feet in diameter. In the larger sizes a double disc is used to give additional strength and stiffness. Let us now briefly note the advantages claimed for this invention by the manufacturers. First—It is lighter than any metal pulley now in use, having only about half the weight of the lightest of these. Second—It is fully as strong in doing its work, and is absolutely free from any danger or breakage. Third—It is perfectly balanced from the moment the rim is drawn into position. Fourth—The lightness of the pulley admits of a far lighter hanger, thus decreasing cost in this way. Fifth—The friction is greatly reduced, enabling a lighter shaft to do the same amount of work. Sixth—A great saving of labor is effected by using the Fulton pulley, when placing it in position, because of its extreme lightness. The Fulton pulley may also be made either crowning or flat, and to run vertically or horizontally as occasion may require.

So far as experience has gone the new pulley is very satisfactory. Experiments are now in progress to test the strength and efficiency to the utmost. These experiments are being conducted by eminent authorities in mechanical science. The Fulton pulley will be manufactured by three well known firms in the United States, the Indianapolis (Indiana) Machine and Bolt Works, The John T. Noye Mfg Co., Buffalo, N. Y., and The Falls River Co., of Cuyahoga Falls, Ohio. Messrs. Parke & Lacy have been appointed agents on this Coast, and it may be that the pulleys will be manufactured also.

SENATOR Hill's mineral land indemnity bill came up in the Senate, with Senator Miller's substitute adapting it to California, so as to allow that State the right to make selections for school lands in the eighteenth and thirty-sixth sections retained as mineral pending over it. By previous agreement with Senator Hill, Miller withdrew his substitute and Hill's bill passed without objection. Miller then asked unanimous consent to take up the California mineral bill and place it on its passage, when, much to his surprise, Cameron of Wisconsin objected. There was no debate, and the bill went over.

A Combined Knife and Pen-holder.

Isaac Phillips of Silver City, Owyhee county, Idaho, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency a combined knife and pen-holder, which is represented in the engraving on this page. An ordinary pen-knife forms the handle, and has in its back near one end a chamber in which a short pen-holder and pen lie. The holder is pivoted to the knife handle in such a manner as to enable it to be opened out with the pen, so that the handle of the knife will then form for it the staff, when the implement is used for writing. A hinged casing or cover is adapted to enclose the pen and its holder when lying within the chamber, whereby the dust is kept out when the implement is carried in the pocket. The object of the invention is to provide a convenient implement capable of being used as a knife or a pen, as occasion demands. One of the views shows the implement with the pen ready for use, and the other shows the pen and pen-holder folded back into the handle of the knife. The advan-

THE FULTON PATENT PULLEY.

tages of such an implement are readily recognized.

MANUFACTURERS' ASSOCIATION.—At a meeting of this association, held on Monday, the Executive Committee reported that they had engaged a room for the meetings of the association in the Merchants' Exchange, at \$20 per month, from the 1st of February. The matter of appointing a secretary who should attend exclusively to business of the association was brought up. Colonel Harney reported from the Finance Committee, to whom the matter

PHILLIPS' COMBINED KNIFE AND PENHOLDER.

had been previously referred, recommending that the salary of the Secretary be fixed at a sum not to exceed \$150 per month. The report was concurred in, and the matter of selecting a secretary was referred to the Executive Committee, with power to act. The Treasurer's bond was fixed at \$10,000, with two sureties in \$5,000 each, and the Secretary's at \$5,000, with two sureties in \$2,500 each, both of said bonds to be approved by the Finance Committee. Lewis H. Sharpe was appointed attorney of the association, and several new members were elected.

COAL.—Last month we received 70,000 tons of coal in this city exclusive of what came from the California mines. The Canton Hill mines (Puget Sound) sent 13,275 tons; Renton (Puget Sound) 3,174 tons; and Seattle (Puget Sound) 9,205 tons. The Coos Bay (Oregon) mines sent 795 tons. From British Columbia mines the following came: East Wellington, 7,600 tons; Nanaimo, 4,245; and Wellington, 10,236 tons. Of Eastern anthracite we got 2,314 tons; and there were 7,494 tons of Australian. The other 20,000 tons came from Europe.

THE Sierra Butte mine produced \$187,59 in December last, and \$212,018 for the year 1883.

Gold and Grain.

Gold and grain, it will be admitted, are important products for the prosperity of a State and people. For the past few years grain producers and operators have considered all that was worth caring for was grain, although gold was in the end the object sought. As English gold could be obtained for California wheat, California's gold product was not desirable. They could deride and kill that, destroying as well the chances of inviting gold for mining enterprises, and thus the loss by gold production and gold that would have come in for mining investments would foot up fully \$75,000,000—taking in the past five years of tirade against hydraulic mining, which, though against one class of mining, has seriously injured all classes. There now seems to be a flatter in the grain camp; the English market rates show too conclusively that failure is to be the fate of grain shippers, even at the low charter rates which as a total has caused to our San Francisco dealers an immense loss. I use

the word immense—I suppose it has a meaning when a single house fails for one and a half million of dollars. The position of affairs now is such that the whole State has not only to suffer by this grain decline, but by the loss of gold which, but for the tirade against mining, would have been produced. It is probably well enough, for the farmer will be convinced by these failures to get English gold of the value of home gold production. If he does not as yet, he soon will be, from the fact that a financial panic is merely a matter of an unsuccessful shuffle with our railroad magnates, and which is not an unlikely event any day as matters now stand in Wall street. Already the more intelligent press sees the impending

During the current year it will probably not amount to 37½ per cent. The fall has been from three-fourths down to three-eighths in four years. This is a tall indeed—a veritable revolution in commerce. The following are the official figures of the imports of wheat and wheat flour into Great Britain from the United States during the calendar years 1881, 1882 and 1883:

	1881, cwt.	1882, cwt.	1883, cwt.
Wheat from Atlantic ports.	21,746,551	20,317,230	14,229,195
Wheat from Pacific ports.	11,241,323	11,712,333	11,806,637
Flour from all U. S.	7,696,415	7,777,352	11,579,913
Totals, cwt.	40,684,289	39,806,915	37,615,745
Totals, bushels.	93,463,387	85,673,770	74,673,500

The importations from the United States, which in 1881 were over 93,000,000 bushels, fell in 1882 to 85,000,000 bushels and in 1883 to 74,000,000 bushels. That this fall is not due to a diminished consumption of foreign-grown wheat and flour in England is evident from the fact that the importations into that country are greater than ever. This is shown by the following table of imports of wheat and wheat flour into Great Britain from all countries during the calendar years of 1881, 1882 and 1883:

	1881, cwt.	1882, cwt.	1883, cwt.
Wheat	57,942,636	61,171,662	64,680,444
Flour	11,360,411	13,028,705	16,233,529
Totals, cwt.	69,303,047	74,200,367	80,913,973
Totals, bushels.	136,806,138	154,400,654	169,747,946

In 1881 the importations of wheat and wheat flour into Great Britain were little more than 136,000,000 bushels; in 1882 they rose to 154,000,000 bushels; in 1883 to 169,000,000 bushels. Thus, while the imports from the United States have steadily fallen off, those from other countries have steadily increased. There can be no doubt about it; King Wheat in America is dethroned. The next question is, Where has he erected his kingdom? Turning to another part of the official accounts before us, we find that the farinaceous monarch has hoisted his standard in Russia and British India, where he now reigns without a regret for his lost constituency in the United States. The imports of wheat into Great Britain from Russia, which in 1881 amounted to 8,000,000 bushels, rose in 1882 to 19,000,000, and in 1883 to 27,000,000 bushels; while those from British India, which were 13,000,000 bushels in 1881, rose in 1882 to 17,000,000, and in 1883 to 23,000,000 bushels.

The above figures may be considered by free-traders indicative of the intention of Great Britain to emancipate herself from her trade servitude to the United States, but they have no such import. They mean simply that the nations whose exports of grain to Great Britain are increasing are able to produce wheat cheaper than the United States can. They manage to do so with the aid of serf labor in Russia, and coolie labor in India. If the farmers of this country were ready to adopt a serf or coolie system, they might be able to withstand the growing competition of Russia and India.

Wheat growers may yet be glad to fall back on to the industry they have sought to destroy. In another respect we are a very smart people. On the one hand we do all we can to induce immigration to California, and on the other all we can to drive more away than these immigration efforts bring. This year, in consequence of our mining troubles, no less than 10,000 people will leave California for Cœur d'Alene mines, Idaho, and other sections. And here an idea suggests itself: The Immigration Society want cheap lands, houses and lots—the miners have lots of them for sale. I would suggest that all miners who want to sell their homes in order to emigrate to the new mines send in to the Immigration Society, No. 10 California St., a list of their property, cost and what they are willing to take for it. This might benefit the emigrant as well the immigrant. It would have one good effect—it would let the business men and press of San Francisco see that while they were settling on the one hand there was considerable unsettling on the other.

With the wheat crop export killed by the Russian serf and India coolie, and the gold crop of California by the California farmer, the general loss in gold will foot up at least \$30,000,000 yearly as long as conditions stand as they do at this time. Can lands enhance in value under such a showing? Can business in San Francisco expand? The fact of it is, this war against mining has got to stop, and every farmer, banker, merchant and manufacturer has got to put in a good word for it, or his own business pays the penalty. The cry that the waters must run clear will probably abate, and it is quite certain now that American wheat is dethroned as king; that when the waters do run clear in front of Sacramento and Marysville that the grass will grow in their streets from the lack of business. I hope that more justice and judgment will prevail.

ALMARIN B. PAUL.

San Francisco, Feb., 1884.

AMERICAN INSTITUTE OF MINING ENGINEERS.

The annual meeting of the institute will be held in Cincinnati on the 19th inst., when the election of officers will take place. The following nominations have been made: For President, James C. Bayles; for Vice Presidents, Eckley B. Cox, Thomas Pileston and Edmund C. Pechin; for Managers (to serve three years), Edgar S. Cook, Frank Firminstone and G. W. Maynard; for Treasurer, Theodore D. Rand; for Secretary, Chas. Kerchoff, Jr., Frederick Prime, Jr., and Rossiter W. Raymond. The address of the latter, who is the present Secretary, is lock box 223, New York. Members in good standing can send to him their ballots, choosing from the above-mentioned names.

storm, and say that mining must be encouraged; that means must be devised to prosecute even hydraulic mining—the country must have the gold. This is all well enough to talk, now they see the great loss through their own efforts to break down mining investments. In this State we are great sticklers for gold coin—everything is for gold, the farmer even works for gold. We have the greatest gold country in the world. We have produced \$60,000,000 per annum, and could produce \$100,000,000 per annum with proper encouragement; and yet the yearly product of 1883 only amounted to about \$18,000,000. What makes prosperity is money, plenty of it, and we in this State are doing all we can to have as little of it as possible; and this a serious matter when the fact is generally known that California grain will no longer bring English gold as in the past. To this end I will introduce the following article from the *Chronicle* of Feb. 2d, and then I will not be accused of creating a false alarm from prejudice. It is very instructive reading for the farmer, and is headed "A Revolution in Commerce."

The "British Trade and Navigation Accounts," received by yesterday's mail from London and containing the official accounts of commerce to the end of the year 1883, contain a genuine surprise. They prove that the supremacy of the United States in the wheat markets of England is definitely over. There can be no mistake about it. King Wheat is as effectually dethroned now, as was King Cotton 20 years ago. Four years ago the United States supplied 75 per cent of England's entire importations of wheat and wheat flour. In 1881 this fell to 69 per cent; in 1882 to 55 per cent, and in 1883 to 46 per cent.

Metallurgy and Ores.

Nevada Metallurgical Works.

NO. 23 STEVENSON STREET,
Near First and Market Streets, S. F.

[ESTABLISHED, 1869.]

C. A. LUCKHARDT.

B. SALAZAR.

Ores worked by any Process.

Ores Sampled.

Assaying in all its Branches.

Analyses of Ores, Minerals, Waters, etc.

Working Tests (practical) Made.

Plans and Specifications furnished for the most suitable Process for Working Ores.

Special attention paid to Examinations of Mines: Plans and Reports furnished.

HERCULES SLAYING THE GIANT.

HERCULES POWDER

Derives its name from Hercules, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

AJAX and VULCAN B B POWDERS are Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

VULCAN POWDER CO.,

218 California Street, San Francisco, Cal.

GIANT POWDER,

MANUFACTURED UNDER ALFRED NOBEL'S Original and only valid Patents for NITRO-GLYCERINE Powders, which has been and still is of such immense advantage to the Miner, Railroad Man and the Engineer. All other Nitro-Glycerine Compounds are simply imitations and adulterations of the Original Giant Powder. The GIANT POWDER COMPANY manufacture three grades of Powder, which are the Safest and Strongest High Explosives in the market. The Original Nitro-Glycerine Compound, GIANT POWDER or DYNAMITE, is acknowledged by all the great chemists of the world as unapproached by any other compound. The GIANT POWDER COMPANY have acquired the exclusive right to manufacture "NOBEL'S EXPLOSIVE GELATINE," which contains 96 per cent of Nitro-Glycerine. It is still stronger than Dynamite, and even safer in handling. This explosive was used in constructing the Mont Cenis Tunnel. THE JUDSON POWDER is a black Powder owned and Manufactured by the GIANT POWDER COMPANY; is from three to five times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it Breaks More Ground, Pulverizes Better, and Saves Time and Money. The only difficulty heretofore experienced by some consumers of this Powder has been that it required more time to get it to the bottom of a deep borehole. This has now been entirely overcome, and our JUDSON IMPROVED is now as dry as the ordinary Blasting Powder and runs as freely.

Triple, Quadruple and Quintuple Caps and all grades of Fuse for Sale.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those intending to Manufacture or Purchase the so-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patent held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

January 3, 1884.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers. \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 232 Market Street, San Francisco.

N. B. This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver; Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with

Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-

visable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plan. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, or sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE ever invented for the service of Prospectors and others requiring the use of a Horse Power, possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower without interfering with a hoisting apparatus.

It is made entirely of IRON; no piece weighs over 250 pounds. At the ordinary speed of a horse a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope. The cost of erection is slight, as two men in half a day can easily put it in place ready for work.

While this power is more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. SEND FOR CIRCULAR. Address

ALL INFRINGEMENTS PROSECUTED.

HYDRAULIC GRAVEL ELEVATORS.

The Great Problem of Shallow Hydraulic Mining Solved.

NEW FIELDS OF ENTERPRISE IN HYDRAULIC MINING OPENED UP.

These machines are thoroughly effective for working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon.

At the property of the Yreka Creek Gold Mining Company, in Siskiyou county, Cal., an Elevator of the Improved Form has been introduced, which, with a head or pressure of water of 266 feet, is elevating through an 18-inch machine to a vertical height of 46 feet from bedrock to upper flume.

Descriptive Catalogues and prices furnished on application to the undersigned, who are the sole manufacturers of these machines.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Manufacturer of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

DOWNIE EUCALYPTUS BOILER SCALE

Preventive and Remover.

(Patented May 8, 1883.)

In use in 1,000 Boilers on Steamboats, Locomotives, Mills, Mines, Foundries, etc., in California. An

Infallible Preventive and Remover of Scale.

Prevents the iron from rusting or pitting.

Shipped in ten gallon cases at 50 cents per gallon, by

DOWNIE B. I. P. CO.,

No. 7 First Street, - - San Francisco.

THE HARMON SEMINARY, Berkeley, Cal.

A BOARDING AND DAY SCHOOL FOR YOUNG LADIES.

This institution will be continued with the spirit and methods of its founders by those who have grown up with them in their educational work. The corps of instructors is full and of recognized excellence in all departments.

Address, THE MISSES HARMON, Berkeley, Cal.,
Or E. J. WICKSON, 414 Clay St., S. F.

The Lemmon Herbarium.

This Herbarium has been removed from the Blake House to a permanent place at 1205 Franklin St., near Fourteenth St., Oakland, one square east of the Post Office, where plants of the Pacific Coast, including Arizona, may be determined on application, and instruction given in botany during the winter. Sets or single specimens of the rare and new ferns of the Pacific Coast for sale.

VOLUME XLVIII
Number 7.

Wood Working Machinery.

Probably no class of machinery has shown so much improvement in the last decade as has that intended for the various processes of wood working. The machines seem to have well nigh reached perfection. The engravings on this page show two forms of surfacing machines, Fig. 1, being a 24-inch Hamilton surface planer, and Fig. 2 a 26 and 30 inch endless bed surfacer; Fig. 3 showing the sectional feed roll applied, or the lathe machine.

The Hamilton surface planer is intended especially for fine, smooth planing to a thickness. The bed carrying four idle rolls, is raised and lowered by screws and bevel gears operated by the hand wheel near the bottom. The feed consists of two feed rolls, one of them fluted, which are driven by gears and belts from the head, and started and stopped by means of the lever which operates an idler. The feed is thus all contained in and supported by the frame, so that the machine may be run without a special countershaft.

An improved pressure bar is situated close to the front of the head, a scraper is attached to the back roller, and the rollers are placed very close together so that very thin and short material may be planed. This is a very desirable feature in a planer, and is especially provided for on this machine, and with triangular shearknife head, the close rollers, etc., very short, thin and smooth planing can be done.

The patent triangular shearknife head mentioned, is driven at one end, carries three knives, and makes a shearing or drawing cut, and as a consequence does very smooth work. Material may be planed 6 inches thick, and as thin as 1-16 of an inch. The weight of the complete machine is 1,200 pounds.

In Fig. 2 is represented the 26 and 30-inch endless bed surface intended for heavy planing, and for dressing rough and uneven material. Instead of the material having only two or four driving points, and the material sliding on a long bed, causing great friction, as is the case with the roll planer in the endless bed planer, the whole bed travels, using the same friction to drive the material that in the other case retards it. The rolls and pressure bars hold the material down firmly, but offer comparatively little resistance to its motion.

The machine shown in the engraving is a heavy one of its kind, and has some new features which add to its superiority. The bed is long and heavy, 26 inches wide, and is raised and lowered in well-fitted slides by means of screws, bevel gears and a hand-wheel, and will lower sufficiently to plane material eight inches thick.

One of the improvements and the chief feature of the machine is the construction of the slides and slats. The slides are of hard steel, and are flat and true. The slats are three times as heavy as usual, being very thick at the top and having a round cored brace underneath. The sliding bearings of the slats are hardened steel plates, arranged to scrape off the dirt that may collect on the slides, and have recesses in the slat above them which are filled with waste and oil, and holes in them through which the oil reaches the slides. With this arrangement the slides and slats are kept well oiled and clean, and the chief trouble with this style of planer is overcome. The cylinder is of the patent triangular shearknife pattern, very large, and runs in extra long boxes. The feed

is driven from the cylinder shaft through an idler shaft, pulleys and gears as shown, and is regulated by means of tightener and pulley.

When the machine is to be used for planing strips or uneven material, the makers furnish Brown's patent sectional feed roll, a very convenient device for the purpose. As shown by the cut (Fig. 3) it consists of a number of sections placed upon a round bar, each section being a ring of rubber of the best quality and very flexible, covered outside with a ring of

Fig. 1. HAMILTON SURFACE PLANER.

iron to protect it from wear. The inside of the rubber ring is hardened so that it will no wear if it turns on the bar, which, however, it will

thick syrup, which, by continued beating, expels water vapors to a large extent, and forms after cooling a hyaline mass. This mass is

Fig. 2. ENDLESS BED SURFACER.

seldom do. This hardening next to the hole, and the iron ring are shown very plainly in both cuts, and the position taken by the roll

soluble in water, and in concentrated solution the boroglyceride can be received in crystals. The boroglyceride is now in use as one of the

Fig. 3. BROWN'S SECTIONAL FEED ROLL.

when feeding uneven material is also shown. The roll will give to very unequal thicknesses of material, and is especially useful for such work as felly strips, etc., and altogether is a very valuable improvement. The weight of the complete machine is about 3,000 pounds.

These machines are made by the well-known manufacturers of wood working machinery, Bentel, Margedunt & Co., of whom Whitney & Marshall, of 22 and 24 Fremont street, in this city, as the sole agents. This firm received the first premium and gold medal at the last Mechanics' Fair in Portland, Oregon, for their display of wood working machinery made by the above named manufacturers.

Boroglyceride.

A new chemical compound, which promises to have a great future, is the boroglyceride. It is only a short time since it was discovered that the boric acid forms with glycerine, compounds analogous to the natural fatty matter or fats, as oleine, palmatine, etc., in which the boric acid replaces the fatty acid; 100 parts of glycerine dissolved by a temperature of 180° to 220° F.; 67 parts of crystallized boric acid to a

Institute of Mining Engineers.

The annual meeting of the American Institute of Mining Engineers, occurs next week at Cincinnati. The proceedings will extend over four days. There will be addresses, reading of papers, visits to works and places of interest, a reception, banquet, etc.

The following papers have been promised for this meeting, besides others partially promised: "Physical Tests of Metals," by Arthur V. Abbott, New York City; "Sulphur Determinations in Steel," by Magnus Troilius, Nicetown, Pa.; "Tables for Facilitating the Heat Calculations of Furnace Gases Containing CO_2 , CO , CH_4 , H and N ," by Magnus Troilius, Nicetown, Pa.; "Further Determinations of Manganese in Spiegel," by George C. Stone, Newark, N. J.; "Note on the Determination of Phosphorus in Iron," by Frank Julian, Iron Mountain, Mich.; "Note Concerning Certain Incrustations on Pig-Iron," by Frank Firminstone, Glendon, Pa.; and Kenneth Robertson, Jersey City, N. J.; "The Phosphate Deposits of Canada," by T. Sterry Hunt, Montreal, Canada; "A Silver Amalgamation Mill," by G. W. Maynard, New York City; "The Test Commission Bill," by Thomas Egleston, New York City; "The Benefit Fund of the Lehigh Coal and Navigation Co.," by Joseph S. Harris, Philadelphia, Pa.

The Secretary calls attention of members to the subject of the last named paper, as one of the greatest importance and interest to mining and metallurgical industries. It is believed that many members of the Institute possess valuable experience in the matter of organizing and administering funds for the benefit of workmen, and that a comparison of opinions and results cannot fail to be generally useful. Members desiring to contribute to such a discussion are asked to notify the Secretary, and send to him their remarks in writing, if they do not expect to be personally present.

Volume XI of the Transactions has left the printer's hands, and that the copies not ordered to be bound will be distributed within a few days. The distribution of bound copies will be somewhat delayed. The Index to Volumes I-X inclusive is in the printer's hands, and a portion of it has already passed through the press. In this case also, the copies not ordered to be bound will be distributed as soon as ready, without waiting for the binding of the rest.

A DISPATCH from Walla Walla, W. T., says: The excitement about the Cienega mines is abating. The most atrocious falsehoods are being disseminated about their richness, when, in fact, old miners believe that not \$5,000 has been taken out since the camp was struck. What little has been seen is of a scaly nature, which occurs in spots. The creek is very flat and deep. No work has been done except on a high rim outside the main channel, in which bedrock has not been seen yet. The claims are 201 acres each.

EXTRA PAGES.—For the present, while our columns are crowded, we shall publish eighteen instead of sixteen pages of the MINING AND SCIENTIFIC PRESS, and shall add several pages as occasion demands. The publishers intend to make the PRESS as interesting as possible, and furnish a full quantity and variety of valuable reading matter.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Mineral Park, Arizona.

EDITORS PRESS:—Thinking some items in regard to mining affairs in this district will be of interest to some of your readers, I send you a few.

The Schuykill mine, at Chloride, is working steadily, and eleven men are mining, sacking and sorting more ore than three ten-mule teams can haul away to Kingman, a distance of nine teen miles. Purchase of the adjoining claim has just been made, and as surface indications on this claim are better than on the Schuykill it is expected that a much larger production of ore will be the result of the working of this mine. The claim was sold by Jerome Burnes to Davis & Potts for the small sum of \$1,250. The deepest shaft is twenty feet, but the vein has been opened at intervals for almost its entire length, and the showing is excellent; in one place there is four feet of solid galena and almost pure white carbonate, sampling from 48 to 51 per cent lead and 24 per cent silver. Work will be commenced at once, and it is expected that the daily production will be double that of the Schuykill. Unfortunately the latter is poorly worked owing to inexperienced management. Like nearly all other mining enterprises that have been undertaken in this district, the Schuykill has the misfortune to be in the hands of persons ignorant of the proper mode of working a mine. In a short time, under the present system, it will be in such a condition as to render it almost an impossibility to prosecute further developments of the mine.

Besides these two mines, P. F. Collins is taking out from two to three tons of lead ore per day, working two men.

The Rattler, which is a forty-foot ledge, showing four feet of lead ore, will start up in a few days, and of course the ore will all go to San Francisco.

There are a dozen other lead mines in this vicinity which have equally as good a showing as any now being worked, but which are lying idle for lack of a little industry.

The Champion mine at Cerbot has been shut down, owing to an injunction being placed upon it by the Champion Con. Co. and S. Mining Co., of San Francisco. This mine has been making regular shipments of galena ore for three months past.

The New London, at Cerbot, has suspended production in order to timber the main shaft, which is down 190 feet, and shows 5 feet of lead ore in the bottom. Other claims at Cerbot are being worked and ore being shipped.

Stockton is shipping considerable quantities of lead and silver ores.

The rich ore in the Cupel still holds out, and everyone in Stockton seems well satisfied with their progressive little mountain camp.

The Mineral Park mill will start up in a few days and run through the tailings now lying at the mill. The company will also start up the Keystone mine at once.

So that on the whole we are slowly but surely coming out of our obscurity, and are beginning to be looked upon with more respect by outsiders. We are not looking for any loom and we do not want any.

PROSPECTOR.

Mineral Park, February 1st, 1884.

A WORD TO MINERS.—The decision of Judge Sawyer, adverse to hydraulic mining, does not directly affect Tuolumne county. We have no hydraulic mines, and therefore the interest taken here in the result of the North Bloomfield suit was purely sympathetic. The result of the suit is likely, in a measure, to redound to the advantage of the mining interests of this section. Tuolumne county is fairly ribbed with gold bearing quartz veins. The stoppage of hydraulic mining will cause a lot of mining capital to be diverted into other fields. What more natural than that it should seek safe and profitable investment in the rich quartz leads of this county. No more inviting field for the mining operators can be found in the world. Our mines are numerous and rich. We have cheap and abundant water power, and our wood and lumber supply is inexhaustible, and is correspondingly cheap. This is a golden moment for our mine owners. They should exert themselves to call the attention of capitalists to the dormant mineral wealth, and the advantages which exist for its utilization in this county. With properly disseminated information regarding our mineral resources it would only be a question of time when Tuolumne would become one of the foremost mining counties in the State. This is no time to sit idle and wait for the wagon. Let our mining men blaze the trail and put their shoulders to the wheel, and we will soon have busy and prosperous times.—*Union Democrat*.

MAMMOTH PROSPECTS.—The prospects at Mammoth are exceedingly good, and the men at work on the mine feel confident of making a nice thing out of their lease. They are getting out fair grade ore, of which there is plenty in sight. It is thought by some that the mine never had a good chance to show what there is in it. But it once made a big display.—*Bodie Free Press*.

The Cœur d'Alenes.

From the Missoula Times of the 24th, we condense the following interesting information about the Cœur d'Alenes: In spite of the rosy pictures of our contemporary it is yet deemed by men acquainted with the new El Dorado that it is yet too early to join the stampede. A man who goes to Eagle City now can do nothing for the next two months. The Times says: Little else is talked of now but mines, and the Cœur d'Alene excitement is rapidly increasing. Missoula seems to be right in the midst of the "theater of war," but strangers arriving from different sections report the excitement fully as great as here, if not greater. Missoula county will witness some stirring scenes this year—the hurrying of thousands to the mines, the phenomenal building of Trout Creek City, and perhaps other towns, and the usual quota of exciting events clustering in a great mining stampede.

Messrs. Tone & Hamilton, of Trout Creek City, were in town last week doing a genuine "loud office business." They were selling lots in Trout Creek City at the rate of five, ten or twelve a day, and Agent Urlin was kept on the jump making out the transfers. In one week's time they disposed of a large portion of their lots, and each succeeding day brought a larger number of applicants than the day before. At this rate they will soon be obliged to lay out additions to the original site. The population of the embryo city is almost doubling daily, and new buildings are going up as fast as men can be procured to do the work.

It seems to be generally undisputed that the Trout Creek trail is destined to be the main thoroughfare to the mines. It is at present the only open route, and is traveled every day.

Incidents of the Stampede.

Although the stampede is scarcely begun, some curious scenes are witnessed on the line of the trail. A gentleman who just came out from Eagle City says he saw several overcoats and bundles of blankets scattered along the trail, or hung on branches of trees. The miners start out from Trout Creek City drawing toboggans loaded with their provisions, blankets, etc., and in their eagerness to get ahead, never look back, and soon getting warmed up, throw their overcoats into the snow, and dash ahead. Some were met with hags of flour, cases of coal oil or loads of bacon on their backs, and one man, named Johnson, was actually pressing forward with a sheet-iron stove on his shoulders.

There are few deer or other game in the mountains about Eagle City, the miners and prospectors having kept up the hunt for fresh meat as long as game could be found. Fish can not be caught at this season.

There are no good tools to speak of in the camp, and the miners are in greater need of good steel picks and shovels than provisions.

When Mr. L. came out he met some fifty going in, nearly all of them drawing toboggans. One man had a load of 250 pounds. He was only six miles out and was already weary, though he had not reached the foot of the mountains.

The Trout Creek trail, over which Mr. L. came, is well beaten for footmen.

A great number of nuggets weighing one, two and three ounces have been found, and several very rich quartz ledges discovered.

Pritchard creek is heavily timbered, and during a storm it is almost as dark as night, and about as dismal a place as can be imagined.

The miners are busy cutting wood, sawing lumber and digging drains.

Alum.

Native Alum.

Alum appears in the form of an efflorescence on argillaceous rocks in the Silver Mountain district, Alpine county, California, but the deposits are too light to be of much practical value. In the early part of 1875 the discovery of what was termed an alum lode was reported to have been made on Howell mountain, Napa county, California. As is often the case with these reported finds, much was claimed for the extent and purity of this deposit; but as a very little alum from that locality ever found its way to market, the first accounts of this discovery were presumably much exaggerated. Some of the springs of the Geysers group, Sonoma county, also small springs near Owen's lake, carry a small percentage of alum. Certain clays found in Santa Clara and Calaveras counties in the same State show a strong taste of alum; but if any valuable deposits of this mineral have ever been found in the Pacific division, the fact has not become generally known. Alum occurs in small quantity at Mount Vernon and in Jefferson county, Colorado. In other parts of the Rocky mountain region small quantities of the mineral are found, but nowhere in economically available bulk.

Artificial Alum.

The alum of commerce is a manufactured commodity, and the supplies consumed in this country are both of the imported article and that made in a few chemical works in the Eastern States, chiefly in Pennsylvania, New York and New Jersey, from alum shale, clay, etc. In the census year ending May 31, 1880, the production of artificial alum in the United States was 39,217,725 pounds, valued at \$808,

165. The production of artificial alum in 1882 amounted to between 16,000 and 20,000 tons, which at 2 cents per pound would be worth from \$640,000 to \$800,000. Nearly all was made from alum clays brought from France and England, but the manufactured product is said to be superior in quality to that imported from England. The process of manufacture is very simple, consisting in mixing the clay with sulphuric acid, dissolving the sulphate of alumina thus formed, and then adding a solution of sulphate of ammonia and crystallizing the resulting salt. The leading manufacturers are Messrs. M. Kalbfleisch's Sons, of New York city and Buffalo; Chas. Lennig & Co., Harrison Bros. & Co., and Powers & Weightman, of Philadelphia, and the Pennsylvania Salt Company, of Philadelphia and Pittsburg.

Academy of Sciences.

Vice President H. W. Harkness presided at the meeting of the California Academy of Sciences, on Monday evening. Donations to the museum were as follows: Ore from Cburchill county, Nev., W. S. Bell; lava which floated ashore near San Pedro, Los Angeles county, Rev. J. C. Nevin; sandstone from ocean beach, D. Barnes; fish, from W. G. W. Harford; specimens of fishes, J. S. Lanson, U. S. Coast Survey; also several bottles of small crabs; from J. H. Merry several specimens of "fluke," or *distoma hypaticum*, found on gall of sheep in Humboldt county, Cal., where many hundred sheep have been killed by them.

Dr. Behr gave a brief sketch of the life history of the distoma. A sheep that has these insects generally fattens quickly and dies suddenly. The liver fluke is an intestinal worm which is harmless to higher animals. Its eggs undergo transformation, and sometimes only one egg propagates out of nearly 4,000,000, the rest perishing before propagation. This distoma multiplies very rapidly, but not in the higher animals. In Egypt there are two other species of the distoma, which cause inflammation in the human eye or bladder.

Dr. Henry Gibbons, after asking to have the reading of his paper on the "Auroral Disturbances" postponed till next meeting, spoke on the phenomenon of red skies. He thought that the red skies at sunset were caused by volcanic eruptions, but the sun has nothing to do with it. There are strata of moist air at very high altitudes, and the redness of the sky is produced by refraction. The sky first appears a bright yellow, but as the sun sinks further the red glow appears. The red rays are the least refractive of decomposed light, but the rays are most refracted at sunset. Mr. Chas. W. Brooks spoke on the same subject, and described the course of the aerial currents around the globe by which volcanic dust might be distributed.

A resolution was adopted to the effect that the California Academy of Sciences respectfully recommend to the Governor of California the re-appointment of Prof. George Davidson as one of the Board of Regents of the University of California on the expiration of his present term of office; and that the Secretary be instructed to communicate this request to the Governor.

Several papers were submitted by title for publication, as follows:

Description of New Fish (*Squalius Lemmonii*), by Miss Rosa Smith.

Description of a New Genus (*Veatchia*), Dr. Asa Gray.

Description of New Anemone (*Anemone Grayi*), by Drs. H. Behr and A. Kellogg.

Descriptions of Three New Species of Plants, by Dr. A. Kellogg.

Description of Eleven New Species of Plants, by Rev. E. L. Greene.

Description of Three New Species of Plants, Mrs. Mary K. Curran.

Description of Three New Geneva and One Hundred New Species of Fungi, by Dr. H. W. Harkness.

Description of a New Mineral, Mr. T. H. Evans.

Astronomical Notes, George Davidson.

These papers will be published in a special "Bulletin" by the academy.

STRIKING OUT.—Twenty-four citizens of Scales Diggings, in Sierra county, have formed themselves into a company or association for the purpose of sending a representative to examine the Cœur d'Alene placer mines in Idaho. A gentleman by the name of William McDonald, an old resident of Scales and a thoroughly practical miner, has been selected as a proper person to investigate and report to the company. He left a few days ago for the mines, so as to be on the ground as soon as water starts in the spring. If the prospect is satisfactory, Mr. McDonald will secure claims, and many of the company will leave for that section in the spring. The company is composed of the following: S. M. Boyce, E. J. Sammons, H. L. Dwight, M. W. Hamm, August Rutishauser, M. B. Barrett, A. Burgan, A. Westfall, W. W. Gibson, W. Helm, P. J. Alley, Henry Kingdom, Richard Hasskins, Jas. Kingdom, Henry Skinner, John Kenny, L. J. Livermore, T. McDonald, H. Kiug, Wm. Johnson, Wm. Scott and F. Cowden.—*Mountain Messenger*.

The Plumas Eureka mine produced \$35,125 in December; and in 1883 yielded a total of \$418,459.

Bird Migration.

There is now being made, over the whole extent of the country, an effort to secure wider and more accurate information on the migratory habits of birds. This is a subject intimately connected with practical agriculture as well as scientific interest. At the first congress of the American Ornithologists' Union, held in New York City, September 26 and 28, 1883, a Committee on the Migration of Birds was appointed. It is the purpose of this committee to investigate in all its bearings, and to the fullest extent possible, the subject of the migration of birds in the United States and British North America. The work will not be limited to the accumulation of records of the times of arrival and departure of the different species, but will embrace the collection of all data that may aid in determining the causes which influence the progress of migration from season to season. For example, severe storms, gales of wind, protracted periods of unusually high or low temperature (for the locality and time of year) are among the atmospheric conditions that are known to exert marked effects upon the movements of birds. The opening of the leaves and the flowering of certain plants, with the correlative appearance of a multitude of insects, are also among the actors that have to do with the abundance of many species. Hence the careful registration of certain meteorological phenomena, and of the state of advancing vegetation from day to day, will constitute prominent items in the record books of the observer.

For the purpose of rendering the result of the season's work as full and valuable as possible, the committee earnestly solicits the cooperation of every ornithologist, field-collector, sportsman and observer of nature in North America. Indeed, a large corps of observers is absolutely essential to the success of the undertaking, and the committee hopes to receive substantial aid from many who profess no knowledge of ornithology. Efficient service can be rendered by those familiar with only our commonest birds, and the committee will gladly accept data concerning any well-known species.

To cover the wide field, the territory of the United States is divided into thirteen districts, one of which is called the Pacific Coast District, and includes Washington, Oregon, California and Nevada, and the Superintendent of this division is L. Belding, of Stockton, Cal. The home of each observer is called a Station, and is recorded by number. All persons who are willing to aid in the work are requested to communicate with Mr. Belding, and they will be supplied with a circular describing in full what data the Union desires to obtain. The Chairman of the committee which has the whole subject in charge is C. Hart Merriam, of Locust Grove, Lewis Co., New York, who has pursued the study of ornithology with zeal and success for a good many years. We hope the Pacific coast will be fully represented in the interesting investigation which is proposed.

THE ALTITUDE OF COEUR D'ALENE.—A gentleman well acquainted with this new camp says of it: The altitude of the district is much less than is generally supposed, and a great deal less than almost any of the hitherto great camps. The altitude above the sea of Lake Pen d'Oreille is 2,000 feet; that of Ratdum, 2,250 feet; and that of Eagle City only 2,300 feet. Cœur d'Alene City has an altitude of about 2,000 feet, at Lake Pen d'Oreille. Snow usually commences to fall in the vicinity of Eagle City about November 1st, and continues until the first of April. Work will be resumed April 1st and continue until the 15th of May, when the freshets, incident to the melting snows, will put a stop to mining for a month or more. It is liable to be pretty wet. Last season an immense amount of water came down from the hills into the gulches, swelling Pritchard and Eagle creeks into broad and very rapid rivers. People would do well to bear in mind that the area of the district named, which has a length of ten miles, is all that has been materially prospected. The other is not yet sufficiently prospected to enable men to know of its character.—*Virginia Enterprise*.

RIVER CLAIMS.—In the matter of the application of William Rablin et. als. for a patent for the Bear River Extension placer mine, the Commissioner of the General Land Office decided, under date of January 6, 1883, that the entry of applicants could not be allowed for the reason that "a narrow strip of land 12,000 feet long extending through sections does not conform as nearly as practicable to the rectangular system of public surveys, and if a contrary construction were given to the provisions of the Act of 1882, they could, in nearly every case, be disregarded and rendered ineffectual by placer claimants." The applicants appealed to the Secretary of the Interior from this decision and on the 13th ult., the Secretary reversed the action of the Commissioner and allowed the entry. This is a wide departure from the rule heretofore prevailing, and is an important triumph for claimants of river claims. The mine in question is owned by William Rablin, J. L. Gould, E. C. Uren and other prominent miners of Dutch Flat, and lies just above the Bear river dam, between Colfax and Cold Run.—*Auburn Herald*.

MECHANICAL PROGRESS.

The Sand-Blast Process for Files.

Since the invention of Mr. B. C. Tilghman, of Philadelphia, in 1870, of the process of ornamenting glass by the attrition of fine sand projected at high velocity against its surface, a great variety of applications of the sand-blast have been made. The inventor successfully employed it in cutting stone for building and other purposes, and it has been found an effective agent in drilling and grooving corundum, cleaning brass and iron castings, frosting and ornamenting silver and electro-plated articles, frosting sheet glass, lamp globes and chimneys, table-glass, etc. Even diamond, the hardest known substance, yields to its action. From ornamenting buttons to cutting tunnels in rock may be given, without departure from fact, as the ascertained scope of its capabilities; but, among all its other uses, there is none which would have been thought to present greater difficulties than that of sharpening files.

The chief obstacle here is the apparent impracticability of confining the action of the sand to such parts as require abrasion; but this has been overcome by a peculiarly constructed machine which throws two or more streams of sand and water at different angles, corresponding to the various markings of the file. Nozzles of various widths and directions may be adjusted to the same machine for sharpening files of different dimensions and degrees of fineness. It might be supposed that the sand would cut the point or fine edge off the teeth, but such is not the case, for smooth files are improved as much as those of coarser descriptions. The sand used is exceedingly fine, and is the waste material resulting from the grinding of plate glass. It is so fine as to be smooth and clean like fine mud.

One of the marked advantages of the sand-blast process is that it not only sharpens the files, but cleans them as well. When the work of cleaning is done by hand after the hardening and tempering, it is not only dirty and laborious, but the rate at which the workmen can clean and dry them is only about three dozen per hour. By this process, after the files leave the sand-blast they go to a boy, who passes them under a jet of hot water, which cleans out the sand and sludge, and the file, being then hot, dries of itself. A machine is now in process of construction by which files may be cleaned at the rate of thirty dozen per hour. There is a machine now in operation in Philadelphia which will sharpen from five to fifteen dozen fourteen-inch files per hour, according to the different varieties and forms, and their cutting power and working qualities are made so greatly superior by this process as to establish this as among the inventions of the highest practical value.

Bisulphide of Carbon as a Motive Power.

A patent has recently been secured by F. W. Smith, which is a device for the use of bisulphide of carbon as a motive power. This liquid boils at 157° Fahrenheit, and the vapor condenses readily at 90°. Its chemical analyses shows that the same amount of liquid should produce about six times the power of water, at a given temperature, the amount of fuel in each case being the same. Numerous attempts have been made, within the past ten years or more, to substitute the vapor of bisulphide for steam. But notwithstanding the manifest advantages which would accrue from such a substitution, all attempts have hitherto proved failures. The present, like other inventors in the field, undertakes to demonstrate that he has perfectly overcome the difficulties which have proven disastrous to those who have heretofore attempted to utilize bisulphide for motive purposes. If he can do so, he has accomplished a most important mechanical desideratum.

The *Industrial News*, published by the Inventors' Institute, of New York, says that the inventor has the process in operation in Philadelphia; the apparatus consists of an ordinary two-horse power steam boiler, the steam of which is applied at low pressure to heat the exterior surface of a small chamber of 40 or 50 gallons capacity, into which is pumped, in the form of a spray, the bisulphide liquid, which vaporizes instantly, producing any pressure required, without regard to the pressure of the steam used to heat it, the vapor pressure being determined by the amount of fluid injected. The vapor from this chamber is carried directly to the cylinder of an ordinary steam engine, producing, with the crude apparatus in use, from eight to ten horse power, the only expense being the fuel for the two-horse power boiler. The exhaust vapor is condensed by the ordinary surface condenser, returns to the tank, and is used over and over. There are no complications about its use. It is claimed that it is more easily managed than steam, and with a better constructed apparatus its effective force would be increased at least 50 per cent above that now shown.

PAPER RAILROAD CARS.—A technical journal on car building says: We do not expect to see either passenger or freight cars built entirely of metal. There are many serious objections to metallic siding, but paper compounds, or paper

in some of its forms, will doubtless be used instead, although for many years wood, from its cheapness, will hold its own against any other substances. We do not apprehend that there will be any considerable difficulty in using substitutes for wood in covering cars, but so long as the wood is the cheapest and is sufficiently strong and durable to answer the purpose, we must content ourselves with speculation in regard to the future. When strawboard can be obtained at anything like the price of wood, the siding of passenger cars at least will be much better made of paper than of wood. The size of the sheets which is easily obtainable, and the firmness with which they can be fastened to the posts, are some of the great advantages in its favor. We suppose, from what we have heard in regard to strawboard and straw lumber, that in time a single panel, extending from the door, around the corner and to the center of the car, and reaching from window sills to the bottom, can be used to good advantage. Such a construction would, of course, greatly increase the strength of the car, would be entirely free from splintering in case of collisions, and would show several other material advantages.

The Rake of Tools.

Give your lathe tools and planer tools also as much rake as you can give them for keenness without losing strength enough for the work to be done. If the top can't be given rake, then it will have to come at the bottom or sides. But if it is at the top, it will have greater tendency for a given angle of cutting edge, to let the shaving come off easily, without any power being needed to curl the latter up or to break it off at short intervals.

The greater the top rake, the greater the diameter of the curl that the shaving makes.

The greater the distance between the test part and the cutting edge, the less rake permissible on a given class of work; because the tendency to dig in will be greater.

Conversely, the greater the rake the shorter the grip on the tool, necessary to prevent digging in, springing and chattering.

As a general rule, there should be as little of the tool as possible projecting between the tool part and the cut.

Sharp interior angles should be avoided, as affording starting places for fractures.

There are some places, as for instance in turning a dove-tailed groove in a shaft, where it is usual to give the tool considerable side reach, and to have a regular corner or angle; but there would really be as much strength and stiffness, and less tendency to break, if there were more of a sweep and less of a sudden turn.

Of course, the heavier the depth of cut, the greater the power needed to side-feed the tool; and the more necessity of giving just the right amount of side rake to help the tool in, without springing or chattering.

In estimating the amount of rake required, there must be taken into consideration the question of whether or not there are soft places in which the tool would be likely to dig. The rake must be estimated for the maximum risk of gouging in.—*Journal of Railway Appliances.*

BRASS FINISHING BY ACIDS.—Many articles of brass cannot readily be finished by the file or by any abrading substances, owing to the intricacies of their surfaces. Especially is this true of brass castings of an ornamental character. But a most elegant finish can be obtained by means of acids, which may be protected, if desired, by means of a lacquer or varnish; the acid finish, however, is generally preferred without the addition of a varnish. If the work to be finished is greasy, it should be cleaned by heating and dipping in acidulated water—vinegar and water, or washing soda in water—and then in clear water. The finishing bath may be either nitric acid two parts, water one part; or one part sal ammoniac, one part sulphuric acid, one part nitric acid, one part water; all by measure, and the sal ammoniac to be dissolved in water until a saturated solution is obtained. The articles should not be allowed to remain in the acid more than ten seconds, then taken out, plunged into clear, cold water, thence into hot, soapy water, and dried in hot sawdust.

A MACHINE FOR MAKING STAPLES has been patented by S. E. Mower, of Milford, Pa. The feeding device operates to feed the wire forward a sufficient distance for the length of an entire staple. The wire is fed into a carriage having a series of receiving seats or recesses arranged about its periphery. A continuous rotary motion is imparted to the carriage, and, after the wire has been fed into one of its seats, a severing mechanism cuts off the length of one staple. The wire thus cut is conveyed by the further movement of the carriage to the bending mechanism, which gives it the customary U shape. The grooves of the carriage are of such a depth that the entire wire is imbedded therein, except at the points, which project above the seat. By the further movement of the carriage the staple is carried against cutters which remove the metal projecting beyond the seat, thus sharpening the legs. An ejecting apparatus is also employed to throw out the finished staple from its seat in the carriage.

The first balcony, or belcony, as it was originally called, was put up in Covent Garden by Lord Arundel in the seventeenth century.

SCIENTIFIC PROGRESS.

The Morality and Science of Hanging.

Executions by hanging, even when confined to the privacy of jail-yards, are revolting to every sensitive mind; but infinitely more so when conducted publicly as is done in many localities. The prior exhibition of the hideous tackle, which is often made, and coarser still, the blundering and horrible manner in which the work is sometimes done, is simply a disgrace to humanity. The baneful effect of such scenes upon a community, even when the work is done in comparative privacy, and with the utmost decorum and skill, was made painfully apparent at the late execution in this city, when thousands of men, women and children were gathered around and completely blocked up the approaches to the jail, and that, too, when every individual in that motley crowd knew before they went there that not a single individual would be allowed to witness the execution without a special permit.

If the death penalty must be inflicted, and that, too, by the revolting method of hanging, would it not be better to make such scenes still more private, witnessed, say, by only the five or six officials necessary for its accomplishment, and an equal number of citizens judiciously selected by the Court rather than by the Sheriff? Let the usual eight or ten score of other witnesses be kept out. The press is probably more to be blamed than any other parties for giving so great publicity and interest to such occasions. The sensational character of the press inter-views published before the executions, and the still more sensational accounts which appear afterwards, pandering to and unnecessarily increasing the morbid feeling which always excites the public mind on such occasions. In no way, perhaps, is the freedom of the press more abused than in its publications in regard to criminal matters generally.

It does seem as if the authorities should in some way have power to protect the public morals. How it is to be done should be a matter of serious consideration on the part of our best citizens. But so long as executions must take place, science, as well as humanity, should be invoked to do all that can be done in that direction to ameliorate the evil.

Looking at the matter from a scientific standpoint, death by hanging is produced in one of the three following ways: 1. By apoplexy, caused by pressure on the jugular vein; 2. by asphyxia, caused by stoppage of the windpipe; 3. by shock of the medulla oblongata, caused by fracture of the vertebral column. In the first two cases death is preceded by convulsions, caused by the cessation of the supply of arterial blood to the muscles, and lasting several sometimes many—minutes. In the third case death is practically instantaneous and painless, and is unaccompanied by any convulsive movement whatever.

These points were dealt with by the Rev. Samuel Haughton, M. D., F. R. S., in a paper on hanging, considered from a mechanical point of view, which appeared in the *Philosophical Magazine* for July, 1866. After carefully investigating the subject, and pointing out the more merciful nature of the long drop as against the short drop, Dr. Haughton recommended that the length of the drop should always be regulated by the weight of the criminal, and be such as to produce death instantaneously. He had ascertained that a shock of one ton dropped through one foot was just sufficient to fracture the interior articulating surfaces of the second vertebra at their contact with the atlas, and that this fracture allowed the shock to fall upon the medulla oblongata so as to produce instantaneous death. Hence he deduces the following rule:

Divide the weight of the criminal in pounds into 2,240, and the quotient will give the length of the required drop in feet. According to this rule a criminal weighing 160 pounds should be allowed a 14-foot drop. If, however, local circumstances do not permit of a drop of the requisite length, Dr. Haughton suggests that a weight should be made fast to the feet of the criminal, so as to enable the required shock to be obtained with a drop shorter than would yield it with the weight of the body alone. The matter, therefore, simply resolves itself into the means of securing a sufficiently powerful initial shock.

Having done our part in pointing out how this may be obtained, we leave the further consideration of the points we have advanced to those who are, or ought to be, responsible for the decorous and considerate conduct of criminal executions. Public decency should not be outraged, and mercy should go hand in hand with justice, even to the bitter end.

A Sensitive Thermometer.

M. Govi has presented to the Naples Academy of Sciences an ebonite thermometer supporting a capillary glass tube. This apparatus, when filled with mercury, does not show any slow elevation or diminution of temperature, but in rapid variations of heat a curious phenomenon is produced. If the temperature increases suddenly, the mercury descends in the tube and then slowly returns to the primitive level. The inverse phenomenon is produced in case of sudden cooling. The explanation is very

simple, and depends upon the approximate equality of the coefficient of cubic dilatation in ebonite and mercury. When the increase of temperature is rapid, the recipient expands suddenly and alone, consequently there is a fall of the mercury in the capillary tube. The ebonite, being a bad conductor, transmits the heat only slowly to the mercury, which requires some time to resume its primitive level. A sudden impression of cold rapidly contracts the ebonite, which crowds the mercury into the capillary tube and thus raises the level. This experiment shows the importance of paying attention to the expansion of the recipient, in reading thermometric indications.

CELESTIAL PHOTOGRAPHY.—The first application of photography to astronomy was made in France. The first Daguerrian image of a heavenly body was that of the sun, which was taken by Fizeau and Foucault, April 2, 1845. Soon afterwards fine photographs of the moon were obtained, in the United States by Rutherford, and in England by Warren de la Rue. In many observatories photographs of the sun have been taken for twenty years, to facilitate the study of the spot and faculae. More recently still, Rutherford and Gould photographed the stars, for the purpose of forming celestial charts, and Draper obtained a successful photograph of the great nebula of Orion. The large solar images, which have been obtained during the few years at Meudon, have revealed phenomena on the sun's surface which are invisible to the most powerful telescopes, and which open an entirely new field of research. By their aid we learn the true form of those elements of the photosphere about which so many different and contradictory assertions have been hazarded. In 1881, the first photograph of a comet with its tail was obtained at Meudon. It revealed curious details of structure and allowed divers photometric measurements, which showed that the tail, in spite of its apparent brilliancy, is from two to three hundred thousand times less luminous than the moon. The preservation of the images, the wide range of sensitiveness in the plates, and the facility of embracing the most feeble as well as the most powerful luminous phenomena, lead Janssen to style the photographic plate the true retina of the savant.

THE INSTITUTE OF CHEMISTRY.—By a bill to be submitted to the English Parliament next session, the Institute of Chemistry, incorporated by an Act of 1877, is to be dissolved, and to be re-incorporated under different conditions. The object of the institute is to encourage a thorough study of chemistry and the branches of science applied thereto, in their application to the arts, to agriculture, to public health and to technical industry; and for adopting measures for the advancement of the profession of chemistry, and for the maintenance of the profession of the consulting and analytical chemist on a sound and satisfactory basis. Admission to the institute is to be by examinations held from time to time, and the members will be divided into fellows and associates, distinguished by the letters F. I. C. and A. I. C. respectively, the assumption of which initials by unauthorized persons is to be punished by a fine of £20. The government body is to consist of a council of thirty-five members, including a president, six vice presidents and a treasurer. The first officers will be those holding office in the old institute at the time the act comes into operation. Power is taken to provide a library, a hall and a laboratory for the use of the members, on any resolution in favor thereof being adopted by the members in meeting assembled.—*Iron.*

CONVERSION OF LIGHT INTO ELECTRICITY.—The conversion of electricity into light is now a fact of every day utility, says Engineering, but the reverse process has been very slow of accomplishment. It has, however, been effected by Herr Sauer, whose sunlight battery has been described in the *Electrotechnische Zeitschrift*. The chemical rays furnish the power, and the battery will only act in sunlight. It consists of a glass vessel containing a solution of fifteen parts of table-salt and seven parts of sulphate of copper in 106 parts of water. In this is placed a porous cell containing mercury. One electrode is made of platinum, and the other of sulphide of silver, and both are connected with a galvanometer. When not in use, the whole is inclosed in a box. When in use, the platinum electrode is immersed in the mercury, and the other in the salt solution; the battery is placed in the sunlight, and the galvanometer needle is then found to be deflected, the sulphide of silver being the negative pole. If the sun is clouded, or any other change in the intensity of the light occurs, it is indicated by the needle. The exact effect produced by the light rays does not as yet appear very clear; but their presence distinctly produces electrical action, and their absence suspends it.

THE BALLOON AS A TELEGRAPH MEDIUM.—A method of signaling by means of electric balloons has been successfully tried in Paris by M. M. Mangin and Baudet. The balloon, made of paper rendered translucent, was about eight feet in diameter, and was filled with pure hydrogen. A swan lamp was fitted inside, and a light rope carrying two copper wires was attached. When the circuit was completed, the whole balloon appeared to be a globe of fire. By switching the current off and on, the Morse code can be spelled out, by which communication can be carried on between distant points,

SAN FRANCISCO:

Saturday Morning, Feb. 16, 1884.

TABLE OF CONTENTS.

EDITORIALS.—Woodworking Machinery; Boro
decider; Institute of Mining Engineers, 117. Passing
Events; Mineral Character of Land; Tamping Explosives;
Good and Bad Roasting of Ore; Salt; Defects of
the Mining Law; Mining Claims and Public Surveys,
120. The Skinner Portable Engine; The Advent of
Man and His History, 121. Financial Results of Hy-
draulic Mining; A New Atlas; The World's Fair, 124.
ILLUSTRATIONS.—Hamilton's Surface Planer;
Endless Bed Surfaces; Brown's Sectional Feed Roll,
117. The Skinner Portable Engine, 120.

CORRESPONDENCE.—Mineral Park, Arizona,
118.

MECHANICAL PROGRESS.—The Sand-Blast
Process for Files; Bisulphide of Carbon as a Motive
Power; Paper Railroad Cars; The Rake of Tools; Brass
Finishing by Acids, 119.

SCIENTIFIC PROGRESS.—The Morality and
Science of Hanging; A Sensitive Thermometer; Celestial
Photography; The Institute of Chemistry; Con-
servation of Light into Electricity; The Balloon as a
Telegraph Medium, 119.

MINING SUMMARY.—From the various counties
of California, Nevada, Arizona, Idaho, Montana, New
Mexico, Oregon and Utah, 125-26.

USEFUL INFORMATION.—Tanning by Elec-
tricity; Oiling the Waves; Twenty-four O'clock; The
Cramp of Belts; A New Enameling Process; Ornamental
Sheet Paper; Sawmills; Metal Springs for Instruments,
123.

GOOD HEALTH.—Deterioration of Sight; Ventila-
tion of Bedrooms; Equanimity and Long Life; To Cure
a Cold; Illusions; Brain Tension, 123.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board, Notices of Meetings, Assess-
ments, Dividends and Bullion Shipments, 123.

MISCELLANEOUS.—The Profits of Mining;
Liquor of Soda; Not a Good Year, 122. Outlook in
Calico Mines, 123.

Business Announcements.

Mining Machinery—F. A. Huntington, S. F.
Pumps and Pumping Machinery—Goss & Dow, S. F.
Sawmill Machinery—Stearns Manufacturing Co., S. F.
Safety Boilers—Rison Iron & Locomotive Works, S. F.
Steel Plates—Edwin Mohr, S. F.
Irrigating Machinery—San Francisco Tool Co., S. F.

Passing Events.

The recent heavy storms have had the effect
of storing up a good big body of snow in the
mountains for the coming season. The result-
ant water will not be as useful as of yore, of
course, since in most places hydraulic mining
cannot be pursued. Still the water will be good
for some gravel mines and many quartz mines.

The excitement about the Cœur d'Alene re-
gion is unabated, and from all quarters we hear
of parties being formed to go there at the earli-
est opportunity. Men are coming into Salt
Lake by hundreds and fitting out for the new
mines. From this State many miners will go,
more especially from the region where the
hydraulic mines have been shut down.

We note elsewhere the withdrawal of the ap-
peal to the Supreme Court of the United States
in the debris case. This is only a form, how-
ever, as the appeal is by no means to be aban-
doned. Another formal appeal will be submitted
in due course of time.

As we write (Thursday) the rain is falling
freely. It looks as if the agricultural commu-
nity was to have a prosperous year.

TOMMY ROGAN tells a Montana paper that
while he was in the Cœur d'Alene country the
miners held a meeting, at which it was voted that
the first Chinaman who ventured into the dig-
gings should be hung, and not having sufficient
rope at the time to swing a man, a miner was
immediately sent out on snow-shoes to Trout
creek, where he bought forty feet of the article
and returned.

Mineral Character of Land.

John F. Krohn applied to the Government to
purchase, under Section 2 of the Act of June
15, 1880, certain mineral land at the junction
of Coarse Gold and Dead Wood gulches, in
this State. The land lies in the vicinity of
valuable mineral lands, but had been returned
as agricultural by the Surveyor-General. Still
upon tender of proof and payment by Krohn,
and protest by Henrietta Colmore, Sylvester
Hecker and Charles Limon, to the effect that
a certain part of the tract was mineral, a hear-
ing was ordered, and the local officers held that
three ten-acre tracts thereof were mineral,
namely, the E. $\frac{1}{2}$, and the S. W. $\frac{1}{4}$ of the N.
W. $\frac{1}{4}$ of the S. E. $\frac{1}{4}$ of section 5, which finding
the Commissioner of the General Land Office
reversed, on the ground that the land had been
returned by the Surveyor-General as agri-
cultural.

At the hearing, gold found on said tract was
produced, there being one nugget weighing
twenty-two dollars, and the testimony showed
that considerable gold had been taken out at
different times, including several nuggets of
greater value. The practical miners testifying
gave it as their opinion that, while the
primitive method of pan-washing would not
pay, the modern hydraulic methods undoubtedly
would. To the contrary is the fact that on
some parts of said tracts cereal crops have been
raised. The Secretary of the Interior thinks it
undeniable that a stratum of soil may cover
mineral deposits of this kind, and yet the de-
posits be valuable for mining purposes. And
he also thinks that the undisputed evi-
dences of the valuable mineral character
of the land above referred to show
that the land is not "clearly agricultural,"
as contemplated by Section 2342, R. S., and
are sufficient to warrant a rejection of Krohn's
application to purchase, in so far as it covers
the three ten-acre tracts aforesaid. The ruling
of the Commissioners of the Land Office has
been reversed, therefore, and Krohn allowed to
purchase the land.

Tamping Explosives.

Efforts are constantly being made to effect a
saving in the quantity of explosives used in
mining operations by systematic application
of the charges. The example is cited of a con-
tractor who in strong rock had reduced his
charges of dynamite and got good effect by
tamping the holes with clay. It is customary
to use little or no tamping with strong explo-
sives; the time thereby saved is regarded as
compensating the cost of the greater quantity
required. Tamping with clay pellets, prepared
by boys beforehand, occupies but little time,
and the more complete combustion of the explo-
sive and the reduced quantity employed, lead
to a diminished vitiation of the air, so that the
men may return to their work immediately
after the blast. In another instance of driving
a heading in stone, a saving of about fifty per
cent of the cost of explosives has been effected
by using dynamite in the strong holes and black
powder in the rest; the proportion in this case
is, on an average, one hole charged with dynamite
to three holes charged with black powder. Mr. George C. Andre, in his "Continental Col-
liery Notes," mentions an example of blasting
in coal which lately came to his notice in
France. The borehole was reduced as small as
possible in diameter for the purpose of distribut-
ing the pressure over a greater length with a
given weight of powder. The latter was used
in a cartridge one inch in diameter, and was of a
quick burning character. The effect was very
good, only a small quantity of "small" being
made. Much has been said and written re-
specting the relative quantities of small coal
made by blasting and by wedging, the advan-
tage being invariably attributed to the latter
method of "falling." But, so far as Mr. Andre's
observation has extended, in carefully man-
aged workings, the advantage has been decidedly
on the other side. Prejudice has led to exag-
geration in this matter, and the evils of "shoot-
ing fast" have been over-estimated.

It was thought the big \$8 assessment on
Northern Belle stock was to pay the \$260,000
judgment to the Holmes Co., but it is reported
in the *Eureka Sentinel* that it is an attempt to
"freeze out" the Holmes people who are large
holders of Northern Belle stock.

Good and Bad Roasting of Ore.

To the experienced metallurgist it is not
necessary to insist on the immense importance
of a thorough roasting of the sulphurated cop-
per ore as a preliminary operation and as a key
to its successful and economical treatment dur-
ing all subsequent processes. To those who are
not professional metallurgists, yet are called
upon to direct important smelting operations, it
may be worth while to point out the far-reaching
influence of this step, so often neglected or in-
trusted to incompetent hands. The difficulties
of smelting poorly roasted ores are innumerable.
The silica of the gangue rock, not finding suffi-
cient oxide of iron to satisfy it, forms a tough,
infusible slag, while the undecomposed sulphide
of iron simply melts into a matte, forming a
low-grade product, which requires an extension
of the subsequent processes with corresponding
costs. The difference in the cost of producing
ingot copper from the same grade of sulphide
ore, in the one case well roasted, in the other
poorly roasted, may easily make the difference
between profit and loss.

An excellent example of this may be cited by
taking certain figures presented by Edward D.
Peters, Jr., from results of work done under his
supervision. They show the cost of putting 9
tons of 8 per cent ore into ingot copper, in one
case the original ore being thoroughly, in the
other badly, roasted:

Comparative Results in Careful and Poor Roasting.

	Well Roasted.	Badly Roasted.
Heap roasting 9 tons of ore, at 50 cents Smelting the same.....	\$4.50	\$4.50
Roasting 2 tons of 36 per cent matte from well roasted ore, 3 roasts, at 50 cents per ton.....	3.00
Roasting 3 tons of 24 per cent matte from badly roasted ore, 3 roasts, at 50 cents per ton.....	7.50
Smelting 2 tons roasted matte, at \$2.50	5.00
Smelting 3 tons roasted matte, at \$2.50	7.50
Producing ingot from last matte.....	14.00	14.00
Total.....	\$40.00	\$85.00

The table of Mr. Peters shows a cost of \$5.44
per ton for the well roasted, and of \$7.22 per
ton for the badly roasted ore, thus showing the
total cost of treatment to be increased nearly
one-third through carelessness in the first opera-
tion. In reality this estimate falls far below the
real cost, as there have not been taken into con-
sideration the serious expenses that are likely
to occur from slicking up and burning out the
furnace, the formation of an increased amount
of foul slag that must be melted, and many
other annoying circumstances, all arising from
the silicious character of the slag, which, in its
turn, has occurred from the imperfect roasting
of the ore.

Salt.

Of all the useful minerals found in the Pa-
cific States and Territories none occur in such
abundance as the chloride of sodium—common
salt. Besides numerous salt springs, ponds and
lakes, this mineral exists in crystalized layers
interstratified with other substances, the whole
forming great mountain-like masses, and the
deposits occupying the beds of dry or nearly
dry lakes or wide extended marshes alkali flats,
etc. Besides the product of these natural
salines, large quantities of salt are made by the
solar evaporation of sea-water, not less than
50,000,000 pounds being produced by this pro-
cess on the bay of San Francisco every year.
The plan of producing salt by boiling in ket-
tles, or evaporating the brine in shallow pans,
by means of artificial heat, the common
methods in most countries and used extensiv-
ely in other portions of the United States, is not
practiced here. The regular strong trade
winds and sunny days of summer answer every
purpose as evaporators.

The consumption of salt on the Pacific Coast,
by reason of the many uses in which it enters,
has always been large. It is employed in a
variety of industries, all having considerable,
and some of them very large requirements. In
the reduction of silver ores, and other metal-
lurgical operations, such as the chlorination of
auriferous pyrites, between 2,000 and 3,000
tons of salt are disposed of here annually. In
dairying and meat packing, and for culinary
and other domestic purposes, and for curing
hides, fish, etc., a great deal more is used.
In various manufactures and in the economic
arts some is also needed, the consumption in
the Pacific States and Territories being ex-
ceptionally large for their population.

A convention of miners is suggested in this city.

Defects of the Mining Law.

Cannot something be done to make mine own-
ers, or rather locators, work their prospects ac-
cording to law? How many miners actually
put \$100 worth of development upon each claim
they own every year? The law requires it, but
is it done? Does not every mining man know
that in each and every one of the numberless
mining districts, from Montana to California,
there are men who hold from one to twenty
locations apiece, and who do not put a dollar's
worth of work upon any of them from one year's
end to the other? Many of these locations
promise well, and might, if a little work was
done, turn out to be paying mines.

As the law now stands, any person willing to
swear that he has performed the annual ex-
penditure required by law can hold his ground,
provided it is properly recorded, against all
comers, no matter if he has not sunk deeper
than the blade of a shovel, or only scratched
the blossom rock with a stick. If the law de-
manded that a 5x6 shaft 20 feet deep, or a 4x6
drift 30 feet long should be the amount of labor
to be performed on each 1,500 feet location in
order to hold it for one year, it would make the
drones and "stove herders" take a back seat,
and give energetic, live men a chance to come
to the front.

Of course the lazy, blumming, verminous
tramp element, whose mining is done at the
street corners and on benches in front of saloons,
will rise up as one man and howl out an al-
coholic tinctured howl that such a law would be
unjust, because some rock is hard, and other
formations are soft. But where one ledge is
found that requires blasting from the start,
there will be dozens that can be sunk to this
insignificant depth with pick and gad. If one
man's ledge requires more powder than that of
his neighbor, it is his misfortune if on that ac-
count he cannot sink to the depth required at
an outlay of \$100; while if the case is reversed
and he has good, soft sinking, so much better
luck.

Any person relocating a mine should be com-
pelled to do a specified amount of work upon it
within sixty days after such relocation; this
would head off a large crowd of Smart Alecks,
who do no work, but hold their claims from
year to year by relocating, and when some en-
ergetic man comes along and perhaps makes a
strike the law which ought to protect him, de-
spoils him of the fruits of his labor and makes
him out a robber.

Mining Claims and Public Surveys.

It has been just decided that where part of a
legal subdivision is non-mineral land, and the
gold deposit is a ravine, a location that follows
the mineral deposit conforms to the public sur-
veys as nearly as practicable. This is the view
of the subject taken by the Secretary of the In-
terior, who reverses a previous decision by the
Commissioner of the General Land Office. It
was in the case of the Esperance mines, near
Marysville, in this State. An area of 41.72
acres is embraced in said claim, and it has
a length of about two miles and a width vary-
ing from eight to seventy feet, embracing the
bed and following the meanderings of a part of the
South Yuba river and Allison's ravine. The ap-
pellant filed evidence showing that the greater
part of the adjacent land is non-mineral, that it
was at the date of location occupied and used
for agricultural purposes, and that the placer
lies between precipitous banks. For these rea-
sons it was urged that the claim conforms "as
nearly as practicable" to the legal subdivisions;
but the decision of the Commissioner repealing
that of May 19, 1873, held to the contrary.

The Secretary of the Interior, however, thinks
that the word "practicable," in Sec. 2331 of
the Revised Statutes, means reasonably practi-
cable, and that in this case it would be unrea-
sonable to require the appellant to conform his
location to the legal subdivision; therefore the
Secretary is of opinion that the claim conforms
as near as practicable to the lines of the public
surveys. The Commissioner's decision was
therefore reversed.

JOHN W. MACKAY will soon leave New York
for this coast, by the Southern route. On his
way home he will stop at the Quijotoa mines in
Arizona, in which he is largely interested.
James L. Flood will go down to Tucson to meet
Mr. Mackay, and they will examine the mines
together.

The Skinner Portable Engine.

The accompanying cut represents the Skinner mounted portable engine and boiler, built by Skinner & Wood, of Erie, Pa. The aim of the manufacturers in the construction of this engine has been to make it simple, reliable and durable. Great care is taken to use a mixture of iron that will produce a cylinder which will longest resist wear, and this result the builders claim has been reached, after careful study, many experiments and large expense, in the cylinder of the Skinner engine. The frame is cast in one piece, with cylinder head and main-shaft boxes, and on the same plane with the center of the cylinder, bringing the strain, if any, in a direct line with the piston rod, avoiding the great evil of the engine getting out of line, which is a common fault of engines built on the usual plan, having their different pieces bolted to the bed. The crank is made of heavy wrought iron and forged solid and slotted. The bed is formed to prevent any drippings from reaching the boiler by the aid of drip-pans, which are placed under the pump, valve stem, shaft bearings and eccentric. These devices deserve special attention, for they insure cleanliness. Every tidy engineer likes his engine and boilers to be clean and neat, and will take pride in keeping them so if the means are put within his reach. With these drip-pans to carry off all the oil and water through one pipe, the operator finds a few minutes' rubbing each morning all that is needed to keep his engine and boilers bright and clean. The valve is a plain slide-valve, cutting off a five-eighths stroke, and driven by eccentric. The valve rod, piston rod, pump and eccentric rods are hammered steel. The valve rod has two square bearings outside of steam chest, with provisions for taking up wear, and between these bearings connection is made with eccentric rod, insuring great durability. The piston has ring packing, which adjusts itself by steel springs, the pins and nuts of which are made of brass, as also is the follower nut, thus preventing rust. The guides and cross-head are of the locomotive pattern, and admit of wear being taken up by both upper and lower guides, thus keeping the cross-head always in line.

The pump is driven by the cross head, has interchangeable brass valves and seats, is thoroughly accessible and every part can be reached without disturbing other parts of engine. The combined check, stop and relief valve is a new feature in this engine, and one every careful engine man will appreciate. The stop-valve being so constructed that when closed, connection is opened between the pump and the atmosphere, thereby relieving the pressure if the pump is started with the valve shut. The engine has a removable piston rod stuffing box, which can be taken out any time by removing the follower nut and check nut; no matter how long it has been in service, leaving the remainder of the engine undisturbed. It is made of steam metal, very heavy and strong, and in using a follower nut to force the sleeve against the packing, the stuffing box can never be crowded out of line, or wear one side more than another. The connecting rod is made of best steel, and at each end are heavy brass boxes, held to rod by bolts. One-half the box is movable, having a projection extending into rod to the key, which takes up wear in the usual way. The box at the crank end has a large chamber for the reception of oil and waste, and at each revolution, sufficient oil for proper lubrication is thrown up through hole in upper part of chamber. This arrangement is very simple and effective, and does away entirely with spring-valves and oil cups.

The governor used on this engine is the Skinner patent automatic stop governor. Most automatic governors require to be readjusted every time the engine is stopped. Not so with this, however; it needs no alteration, or adjustment, unless the belt breaks or runs off. The operation of this device is positive, as all of the automatic mechanism is suspended on frictionless bearings and cannot become ineffective. The framework, gearing, etc.—in fact nearly every piece used in constructing this governor, except base and halls—is made of malleable iron and steel, and the result is a machine which insures strength, is light and of symmetrical proportions.

The boiler is built upon the principle of the stationary arch boiler, having all the advantages of the stationary boiler—safety, effective steaming qualities, ease of cleaning flues, adaptability to all kinds of fuel, etc.—and at the same time none of the disadvantages of the locomotive and vertical boilers. It is made of the best wrought iron, C. H., No. 1, shell one-quarter inch thick, with three-eighths inch flange heads and three inch lap-welded flues. Instead of brick walls this boiler has a heavy wrought-iron casing, built its entire length on both sides, and with fire-brick made especially for the casing, which are clamped to the side of the fire-box. A recent improvement has been made by the builders in placing between the bricks and the casing a heavy lining of fire-proof material, which prevents radiation and keeps the casing cool. The fire is built directly under the body of the boiler, and after passing along its entire length returns again through the flues. The fire-box is very large in proportion to the size of the boiler, admitting the use of fuel that could not be used in any other small boiler. This feature is found of great service in wood-working estab-

lishments, as there is always a large amount of refuse in these shops too fine for use in the ordinary boiler with small fire space without constant firing and attention, while in the above boiler the furnace will hold a large charge sufficient to hold steam permanently. The adjustable and smoke consuming bridge wall is a specific feature found in no other boiler and covered by letters patent. It can be moved backward or forward, enlarging or contracting the fire-box and adapting it to any fuel. The air passes from below up through this bridge wall, where mingling with the smoke, produces flame instead of permitting the gases to pass up the stack unconsumed. No spark arrester is needed with this boiler, which is one of the important advantages secured by the return flue principle, and has made this boiler a great favorite throughout the Eastern States.

No cheap or inferior metal is used in either engine or boiler, and while no attempt has been made to compete in price with the well known cheap grade of engines and boilers, yet a comparison, it is believed, will testify that excellence after all is not incompatible with a low price. Plans are furnished with each outfit showing the length and location of every pipe, so there need be no trouble in getting the pipes in their proper places.

Engines are furnished either mounted or detached as preferred by the purchasers. Every part of both engine and boiler is illustrated, numbered and prices annexed in their catalogues, for the convenience of users in ordering repairs, should they be needed at any time. All parts are interchangeable and duplicates kept in stock at the works. Special care and attention is given to this department, thus avoiding any

THE SKINNER PORTABLE ENGINE.

serious delay in getting new parts should an accident occur.

Hundreds of these engines are in daily use in printing offices, machine, carpenter and wagon shops, cheese factories, grain elevators, mines, etc., in the Middle, Southern and Western States, all, without exception, giving perfect satisfaction, as the many testimonials sent the manufacturers will show.

The Stearns Manufacturing Company, of Erie, Pennsylvania, builders of single, double and triple, saw mills, iron gangs, Pacific screws and self-receding head blocks, heavy automatic and slide-valve engines; stationary and portable boilers, and general saw mill machinery, have lately established a branch house at 21 and 23 Main street, San Francisco, and have the sole agency for the sale of the Skinner engines and boilers on the coast. They are now on exhibition at the above sales rooms, and all interested are invited to call and inspect them, or write for further information and catalogues.

TIN MINE.—A dispatch from Charlotte, N. C., says: Great excitement prevails at King's Mountain, a village about twenty-five miles from here, over the discovery of a valuable mine of tin ore. The first piece assayed yielded seventy-three per cent of pure tin, while others gave an average of forty-three per cent, or 870 pounds of tin to each ton of ore. The tests were made at the United States assay offices. The veins will pay handsomely. Real estate in the neighborhood has advanced six hundred per cent, and the village people have formed a stock company, and have secured all lands believed to be penetrated by ore veins. Several Northern capitalists have promised to advance all the money necessary to construct factories at once.

A NEW building 90x200 feet is being built, in which the Judson Manufacturing Co. will put their tack machinery, so as to increase the product. The present tack factory will be used for extending the Victor Mower Works.

The Advent of Man and his History.

EDITOR'S PRESS.—During the Champlain epoch we find the first reliable evidence of the existence of man, our Creator's latest and most wonderful work, endowed with thinking, reasoning, inventive and creative faculties, such as no other animal possesses. His advent was undoubtedly heralded by great physical changes in the condition and structure of the earth. His remains, with works of art, are found associated with fossils of the mammoth mammals that were at his birth still in existence, but rapidly passing away, as the appearance of man, his superior in intellect, if not in proportion, sounded his death knell and the signal for the disappearance of his predecessor. The world was not large enough for both.

Man evidently at that time was a savage of the lowest type. He had not learned the strength of his power; he was ferocious, and lived by preying on animals of lesser strength ("the fruits of the chase"). His abode was caves and natural openings in the earth's crust. This was the infancy of his species. We next know him by his progressive works of art and implements of the chase and war. His reasoning faculties had taught him that artificial dwellings of stone and earth were more comfortable habitations than his subterranean retreats, as well as by other evidences of reasoning and creative powers that the brute creation were not possessed of. The stone age was rapidly followed by the age of bronze, culminating with the present, the iron age. We

other planetary systems, and unerringly foretells astronomical changes to occur.

"No pent-up Utica confines his powers—
The whole unbounded continent is ours."

The scope of his creative and inventive powers seem almost unlimited. Through the medium or assistance of the spectroscopic and microscope he furnishes an analytical test of the chemical properties of our light and heat-giving power, the sun. His telescope assists his visual organs. The moon's landscape, its mountains and valleys are plainly seen. Saturn's rings and Mars's fiery hue are familiar objects to his near view.

Such is man of the present age, studying to solve nature's great secrets—onward and upward, still reaching out and striving for a higher step on the ladder of fame and science. His ambition is unbounded, and will indomitable—never content and never satisfied. Has he reached the zenith of his power, the culminating point, like the mammoth mammals of the tertiary, whose maximum power and strength proved the signal of their destruction and decay? They had reached the turning point of their existence.

Man has attained a high standard of culture. Civilization and refinement will be continue to progress, or, by some great convulsion of nature or cataclysm of force, be exterminated, and a new era appear—a new form of life brought into existence, as much superior to man as man is to his predecessor. Reasoning from analogy, the future man or being should be as much superior to the present as the present is to the large mammalian brute of the tertiary, which also surpassed in a marked degree the fauna of his predecessor.

In connection with this history, it is in order to state that our former learned State Geologist, Prof. I. D. Whitney, supposed that he had made the wonderful discovery of the pliocene man, anti-dating the "man we know" by a large majority, on which Bret Harte very happily gets off his well-known squib on the celebrated Calaveras skull.

The writer having had occasion to visit Angel's Camp, in Calaveras county, shortly after the discovery of Whitney's pliocene Calaveras skull, which created such an excitement in the scientific world, and being somewhat of an amateur in scientific pursuits, he decided to interview the discoverers. He called on them at their cabin, and was invited to partake of "pot luck" (pork and beans), and during the meal these festive miners seemed in high glee and talking of a nice job that they had put up on "Old Whitney," as they irreverently termed him. It seems from this conversation that they had found an old and very antiquated looking skull (probably that of an Indian) in some shoal places where they had been working, and as a joke took it to the resident physician of the camp (Dr. Fisher, I think) and represented that it was found at the bottom of a deep shaft which they had been sinking; they not for a moment thinking that it would set the whole scientific world agog and render themselves famous as discoverers of so important a find. The doctor to whom the skull was taken, implicitly believing the statement, sent the skull with its history to Prof. I. D. Whitney, who was in San Francisco at the time. Prof. Whitney immediately proceeded to investigate its origin, he visited and examined the shaft from whence the skull was said to have been taken, and decided that it was undoubtedly pliocene and the earliest evidence of man on earth. A cruel hoax.

N. MAN.

LXOTYRE.—This is the name given to the latest development of the photographic art by its inventors, Messrs. Brown, Barcus & Bell, of 31 Bolt street, Liverpool, who have forwarded us some examples of the results of the new process. We are not in possession of the details, but it is stated to be a process by which a printing block, etched or engraved on zinc, and ready for use on any printing press, can be produced by photography and machinery from any object which can be photographed, this being done without the aid of a draftsman or engraver. The manipulation is said to be so rapid as to render the process applicable to the illustration of daily newspapers. The specimens sent, which consist of views and portraits, are soft and effective, and although they are not to be classed amongst high art illustrations, they nevertheless indicate the process to be available for general purposes, and especially in connection with newspapers.—*Iron*.

OUR FROZEN MILLS.—The present intensely cold weather keeps the wheels of the mills on the Carson river locked in ice. In the valleys along the streams it freezes much harder of nights than it does up here on the mountain. A mill using water from the Sastro tunnel would be all right at this season, even when the mercury was frozen solid. As things are, our people can only bide their time, and consider how much better off they are than our fellow countrymen on the Ohio river.—*Virginia Enterprise*.

The new Arizona mining camp, Quijotoa, is becoming civilized. It now has a justice of the peace, a lawyer, an assayer and two deputy sheriffs. The Arizona papers say for men not to come to that camp looking for work. There are plenty of men there now.

OUR readers who are thinking of coming to Colorado for work had better stay at home.—*Colorado Mining Review*.

The Profits of Mining.

Mining must pay. It does pay. There is no business of its magnitude that requires so little capital at the outset. It sometimes uses up a good deal of money before there are any returns, but this money is contributed voluntarily by a confiding public, always willing to risk a little in Fortune's wheel. The laws concerning the occupation of mineral lands are very liberal. There is trouble in finding good locations, but comparatively little trouble in securing the right to occupy and work them. The location secured, the only other thing to do is to incorporate and go to work. It is just as easy to incorporate with \$10,000,000 capital as \$1,000,000, but it is hardly necessary to mention that circumstance in these days, when so many mining companies parade their \$10,000,000 capital on paper. There is no difficulty in getting money to work a mine whose merits can be demonstrated. The means for working many claims are obtained solely through a belief that they will turn out well. There may be the poorest kind of reason for such a belief, but reason sometimes has little to do in the matter. The main point is to work the stock to advantage, and there will be plenty of capital to work the mine.

It is sometimes said that for every dollar got out of the mine in the way of legitimate profit, a dollar has gone into the mine in defraying the cost of working the same. Mining is justified even under that poor view of the situation. The enterprise, as thus carried on, entails no loss, and at the same time it feeds and clothes thousands of the human family, and indirectly vivifies many branches of business. The old dollar put into the business does not lose its identity, and when it again comes to the surface it brings with it a new dollar, and so we have two dollars where we had only one before. Now if the old dollar did any good in feeding and clothing those who earned it, the dollar created by its use will just double the ability for feeding and clothing those who come after it. If he can be called a benefactor who makes two spears of grass grow where before there was only one, the miner who doubles the number of specie dollars in the world is certainly entitled to an equal amount of credit. Besides the wealth which he creates has a greater permanence, since coin outlives many other human products, and is thus a source of perpetual joy and blessing.

Perhaps if capitalists had been asked on the 1st of January, 1883, to contribute \$100,000,000 in order to produce the \$100,000,000 in gold and silver taken out of the mines in 1883, they would have declined the proposition with thanks. The miners understand this thing, and do not solicit capital in that way. They have gone about their business in a more quiet and effective manner. They have developed the \$80,000,000 or \$90,000,000 or \$100,000,000 in gold and silver without creating any alarm among capitalists that they were giving an old dollar for a new one. Many claims paid dividends last year without a dollar's cost to the owners. Others paid their own expenses from the proceeds of the ore taken out and worked. Others paid in part and stockholders made up the difference by assessing themselves for the required amount. Still others had to be worked entirely on the assessment plan. Thus far the gold and silver discoveries of the country have been almost all found in that section west of the Mississippi river. Below will be found a list of the dividends paid in 1883 by the incorporated gold, silver and copper mines of the country, from our own records and from other sources:

Arizona.

	Dividends.	Amount.
Contention Consolidated.....	6	\$375,000
Copper Queen.....	4	300,000
Silver King.....	7	175,000
Total Wreck.....	1	50,000
Total.....	18	\$1,100,000

Five of the Contention dividends were paid in the first five months of the year, and the last in December. The Copper Queen paid quarterly. The Silver King paid six dividends in the first six months, and the other in December. The Total Wreck paid its dividend at the East in the early part of the year.

California.

	Dividends.	Amount.
Black Bear Quartz.....	2	\$12,000
Bonanza King.....	2	41,000
Bulwer Consolidated.....	5	35,000
Idaho Quartz.....	7	34,100
Indian Springs Drift.....	1	1,000
Jackson.....	1	5,000
Napa Consolidated Quicksilver.....	1	10,000
Mt. Pleasant.....	3	90,000
Plymouth Consolidated.....	7	350,000
Plumas Eureka.....	2	40,625
Sierra Buttes.....	2	61,250
San Francisco Copper.....	2	5,000
Standard Consolidated.....	13	325,000
Total.....	48	\$1,009,976

The Black Bear Quartz paid in May and December. The Bonanza King paid one dividend at New York a few months ago, and the other at San Francisco in December. The Bulwer Consolidated paid four of \$5,000 each in the first four months, and one of \$15,000 in July. The Indian Springs Drift paid last February and the Jackson last March. The Napa Consolidated Quicksilver paid in November, and is the only Quicksilver Mining Company in America that paid a dividend last year. The Mt. Pleasant is credited with \$30,000 in December, and \$60,000 previously. The Plymouth Consolidated commenced in June and paid \$50,000

per month for the remainder of the year. The Plumas, Eureka and Sierra Buttes paid semi-annually in London. The San Francisco Copper paid last January and February. The Standard Consolidated gave an extra dividend at Christmas.

Colorado.

	Dividends.	Amount.
Amie.....	1	\$25,000
Bassick.....	2	200,000
Boreel.....	1	18,000
Carbonate Hill.....	2	60,000
California.....	1	7,500
Catalpa.....	1	16,250
Colorado United.....	1	10,000
Dunkin.....	1	10,000
Evening Star.....	2	50,000
Henrietta.....	1	27,000
Iron Silver.....	3	300,000
Little Chief.....	1	20,000
Leadville.....	4	80,000
Morning Star.....	3	75,000
Prussian.....	1	15,000
Silver Cord.....	3	225,000
Smuggler.....	3	42,000
Total.....	31	\$1,200,750

The above mines are all incorporated in Colorado or New York, where most of the dividends are paid. The California, Colorado United and Henrietta are London incorporations, where the dividends are paid. The Silver Cord is a Philadelphia incorporation, and the dividends are paid there. The Smuggler is a Leadville incorporation. These Colorado dividends are copied from the New York *Mining Record*.

Dakota.

	Dividends.	Amount.
Deadwood-Terra.....	1	\$20,000
Father de Smet.....	5	100,000
Homestake.....	12	525,000
Total.....	18	\$645,000

The Deadwood-Terra paid last January and the Father de Smet in January, February, April, July and December. The Homestake paid 40c per share in the first nine months and then 20c per share.

Georgia.

The *Mining Record* credits Consolidated Gold with six dividends of \$4,000 each, the last one being paid in October.

Idaho.

	Dividends.	Amount.
Castle Creek.....	7	\$34,000
Holyoke.....	7	43,000
Juniper.....	1	2,000
Shoshone.....	1	3,000
Total.....	16	\$85,000

These Idaho dividends are extracted from the *Mining Record*. That of the Juniper was paid in December. Idaho promises to do still better in 1884.

Michigan.

	Dividends.	Amount.
Atlantic.....	1	\$30,000
Calumet & Hecla.....	4	2,000,000
Central.....	2	60,000
Osceola.....	3	150,000
Quincy.....	2	380,000
Total.....	12	\$2,670,000

The Calumet & Hecla leads all other mines in dividends at present.

Montana.

	Dividends.	Amount.
Boston & Montana.....	1	\$10,000
Hecla Consolidated.....	12	180,000
Hope.....	3	67,824
Lexington.....	1	220,000
Original.....	12	36,000
Total.....	39	\$513,824

The Lexington is a French corporation and its first and only dividend was paid in Paris as above. The Hope pays in St. Louis and the Boston & Hecla in Boston. The Original pays at Butte.

Nevada.

	Dividends.	Amount.
Indian Queen.....	1	\$15,000
Kentuck.....	8	24,000
Mt. Diablo.....	4	50,000
Navajo.....	5	125,000
Northern Belle.....	4	160,000
Richmond Consolidated.....	3	270,000
Total.....	25	\$584,000

The Indian Queen pays in Boston and the Richmond Consolidated in London. The Kentuck paid in the first seven months and again in December. The Mount Diablo paid its first and only four dividends in the closing months of the year. The Navajo has not been paid since May or the Northern Belle since April.

New Mexico.

The only dividend mine in New Mexico, so far as this office is advised, is the Sierra Grande, which paid five dividends of \$500,000 in Philadelphia last year.

Utah.

	Dividends.	Amount.
Christy.....	2	\$12,000
Crescent.....	2	120,000
Cosmopolitan.....	1	50,000
Horn Silver.....	4	1,100,000
Ontario.....	4	300,000
Total.....	13	\$1,582,000

The Christy paid in January and February, and the Ontario in January, and in the last three months of the year. The Horn Silver pays quarterly in Boston. The Cosmopolitan and Crescent pay at Salt Lake.

Foreign Mines.

The Jocuissita mine in Mexico is largely owned in this city, and paid four dividends of \$200,000 in 1883. The Oxford gold mine in Nova Scotia paid three dividends of \$15,000 last year.

Recapitulation.

Annexed is a condensed statement of the above dividends, showing the number of mines contributing to the grand total:

Locality.	Mines.	Dvds.	Amount.
Arizona.....	4	18	\$1,100,000
California.....	13	58	1,009,976

Colorado.....	17	31	1,200,750
Dakota.....	3	18	645,000
Georgia.....	1	6	24,000
Idaho.....	4	16	85,000
Michigan.....	5	12	2,670,000
Montana.....	5	39	513,824
Nevada.....	6	25	584,000
New Mexico.....	1	5	500,000
Utah.....	5	13	1,582,000
Total America.....	64	231	\$9,915,050
Mexico.....	1	4	200,000
Nova Scotia.....	1	3	15,000
Totals.....	65	238	\$10,130,050

As will be seen, the above dividends have come out of 66 mines, scattered in eleven States and Territories in the United States and two outside. We regret that we have not as complete a record of assessments for the same year. We have endeavored for many years to keep a record of the assessments on all companies publishing their notices in the San Francisco papers, but of course this does not include all the mines in the Pacific States and Territories, and it does not include any of the mines in Colorado, Montana, Michigan or Georgia. It may be that there are no assessment mines in those States. So far as known the Colorado mines are all unassessable.

According to a statement of assessments becoming delinquent in 1883, published in the *Bulletin* and in the *MINING AND SCIENTIFIC PRESS*, Jan. 17th, the gross amount called for by 148 mines was \$5,885,084. Conceding that all this money was collected—which we know was not the case—there would still be a large margin profit on the business as a whole, since over against these claims from 148 mines we have a record of upwards of \$10,000,000 in dividends from sixty-six mines. Apportioning the assessments in 1883 to the States and Territories paying dividends in that year, we have the following comparison:

	Assessments.	Dividends.
Arizona.....	\$165,500	\$1,100,000
Alaska.....	20,250	
California.....	1,196,044	1,009,976
Colorado.....		1,200,750
Dakota.....	10,000	645,000
Georgia.....		24,000
Idaho.....		85,000
Michigan.....		2,670,000
Montana.....		513,824
Nevada.....	4,244,400	584,000
New Mexico.....		500,000
Utah.....	52,000	1,582,000
Total American.....	\$5,088,284	\$9,915,050
Lower California.....		4,500
Mexico.....	193,000	200,000
Nova Scotia.....		15,000
Total.....	\$5,885,784	\$10,130,050

It is possible that some assessments on Arizona mines have been omitted, while it is morally certain that in the case of one or two included in the above total, the money called for was not all collected. Some time ago an Arizona paper stated that the Grand Central mine had paid several dividends this year, but our last record of a dividend for that mine was in December, 1882. The showing for California in the above table is not flattering, but the actual facts, if they could be brought out, would be more favorable. It is known that the assessments on the Noonday, North Noonday, and Red Cloud mines, included in the above total, and nominally amounting to \$300,000, were not collected, and the creditors had to take the mines to cover their obligations. It is probable that some of the assessment money credited to Nevada was not collected. But we are satisfied that poor as last year is considered to have been, the mining industry paid its way quite as well as any other having no more capital at stake, and that the profits were quite as good as most classes of business showing no larger volume. It will be noticed that we have not recorded a single dividend from a California gravel claim in 1883, and these claims must have made some money, despite all their drawbacks, from the litigation growing out of the debris question. The gravel claims will not be entirely abandoned, though at present apparently deserted.

The dividends for 1883 make prominent the copper industry of the country. The Michigan copper mines disbursed nearly 25 per cent of the above total. One of these claims paid \$2,000,000 of the \$2,670,000 paid by the whole six. This is the Calumet and Hecla, which is reported to have paid its stockholders to date the magnificent sum of \$24,350,000. In the earlier years of its history this mine collected \$1,200,000 from stockholders. In the matter of the amount of dividends paid, the Calumet and Hecla stands third in the record of American dividend mines, it being outranked only by the California and Consolidated Virginia. An Arizona copper mine paid \$500,000 in dividends last year, and a California copper mine paid \$5,000. Thus it will be seen that 8 copper mines paid \$3,175,000 of the \$9,915,050 paid by the 64 mines in this country last year. Outside of the copper interests the Utah mines show the best record of dividends for 1883. The Horn Silver and Ontario mines in that Territory have proved to be valuable properties. The dividend record for 1883, so far as we have been able to trace it, compares as follows with the previous two years:

Mines.	Dividends.	Amount.
1881.....	60	\$13,653,400
1882.....	64	13,308,150
1883.....	66	10,130,050

It is hoped that the year 1884 will show a larger total of dividends than 1883.—*Bulletin*.

The total shipments to San Francisco of coal from the Carbon Hill mines, Washington Territory, during the past year was 140,135 tons.

Carbonate of Soda.

This mineral abounds throughout most parts of the Great basin, the extensive alkali flats which form a feature of that region constituting the principal sites of these deposits, which occur usually in the form of an efflorescence an inch or two thick on the surface, but sometimes in strata a foot or more thick imbedded in the earth, and separated from each other by thin seams of clay. When found in the form of a thin incrustation on the surface it is never pure, being always admixed with salt, borax, lime, magnesia, and other minerals. The heavier deposits are comparatively free from foreign matter, carrying generally about 90 per cent carbonate of soda. One of the most remarkable repositories of this mineral known consists of a circular basin, the bed of a former lake situated on the southerly margin of the Forty-mile desert, Churchill county, Nevada. This basin, which covers an area of ten or twelve acres, is depressed 60 feet below the common level of the country adjacent. Its bottom, usually dry, though in wet seasons covered with a few inches of water, is composed of a compact mass of the carbonate of soda so hard that it has to be broken out with crowbars, and so pure that it can for many purposes be used to advantage in its natural state. This substance occurs here in layers about one foot thick, separated from each other by thin seams of clay. Large quantities of the crude material are extracted every year. Some of this is used as it comes from the mine in the beneficiation of silver ores, much the greater portion however being refined and sold for other purposes. The process of refining is effected by placing the raw soda in reverberatory furnaces and subjecting it to a heat of 500° Fah., whereby most of the moisture and excess of carbonic acid it contains are driven off. This deposit has been worked over an area of several acres to a depth of 10 or 12 feet without showing any signs of exhaustion. The receipts at San Francisco during the two years ending with June 30, 1882, amounted to 16,457 centials.

Bicarbonate of soda, nearly pure, is said to occur in a large bed 30 feet thick and covering an area of over 300 acres, in Carbon county, Wyoming. No analyses of the soda are published, and in the absence of positive evidence it seems probable that the soda is in the form of sulphate, containing some bicarbonate. From the lake near Pacific springs, Carbon county, a portion of the salt showed:

Sodium sulphate.....	\$1.23
Sodium bicarbonate.....	14.32
Sodium chloride.....	3.95
Total.....	100.00

From two miles east of Independence Rock, in the Sweetwater valley, the deposit contained:

Sodium sulphate.....	73.17
Sodium bicarbonate.....	22.98
Sodium chloride.....	3.85
Total.....	100.00

Mr. Bailey, Territorial Geologist of Wyoming states that in a distance of 75 miles from Independence Rock there are over 100 soda lakes, which vary in area from 20 to 300 acres and in depth from 15 to 45 feet, and that the soda occurs as a mixed carbonate and bicarbonate.

Not a Good Year.

We would rise to remark and stand up to explain that this will not be a good year for silver mining companies formed on the wildcat plan. The feeling is again 'em. An old bull on Wall street, who has bought a little of everything ever sold on earth, was saying the other day: "Gentlemen, if a man says silver stock to me he has got to die!"

"Don't you believe the prospectuses?" "If President Arthur had his name to one, and General Grant, Jay Gould and Russell Sage guaranteed the stock worth twice its face value, I wouldn't pay ten per cent for it!"

"But there is paying silver stock." "Possibly; but I should want to see the hole in the ground; I should want to go down the shaft; I should want to reach up and knock down half a ton of the stuff, carry it to the assayer, hold a cocked revolver to his head, and have his certificate written on parchment, before I would invest a dollar. Then, before I could credit the fact of a dividend, I should want some one to swear that I was sane, two others testify that I was sober, and a fourth man spike the money down to the table, so that it couldn't blow away!"—*Wall Street News*.

COINAGE OF THE MINT.—The coinage of the San Francisco Mint during the last month amounted to \$1,910,000, of which \$1,660,000 was in double eagles, \$200,000 in standard dollars and \$50,000 in dimes. From July 1, 1883, to January 31st, the Mint's coinage amounted to \$9,756,000, of which \$6,040,000 were in double eagles, \$416,000 in half eagles, \$3,250,000 in standard dollars and \$50,000 in dimes. In addition, the mint coined for the Hawaiian Government \$300,000 in Hawaiian half dollars and \$125,000 in Hawaiian quarter dollars last November and December.

The case of the New York Mining and Milling Company vs. the Amador Mill Tunnelling and Mining Company has been dismissed by Judge Sabin in the Circuit Court. The suit was brought by the plaintiff on account of a dispute over 600 feet of ground between the two parties.

Outlook in Calico Mines.

The general outlook of the mines of Calico district is improving considerably of late. The principal mine in the camp, the Silver King, is looking better than ever. The lowest operations in the mine are at a depth of nearly six hundred feet, and from that level a large quantity of rich ore is being taken daily. The evidences are increasing daily that the mine is becoming richer as work continues downward. It will be years before the present bodies of ore now known to exist in the mine are exhausted. There are seventy men to work, and everything is progressing systematically and smoothly under the satisfactory management of Mr. D. Bahten, Superintendent of the mine. The Bismarck is still turning out ten or twelve tons a day of ore that pays the company a good profit, and the Humburg is constantly quarrying out ore in large quantities and increasing the small mountain of the same on the dump, which at the lowest estimate is valued at about \$250,000, which will warrant the erection of a mill by the owners, and which is still in contemplation. The Garfield has a good force of men at work, and continues to sustain its reputation for excellence by turning out thousands of dollars of silver bullion every month. Mr. Raymond, the owner of the Garfield, is making arrangements to commence operations on the Occidental, which once looked so well, but which has been lying idle. It is the opinion of many that this mine will again show up well if properly mined. The Little V never fails to give good returns from every shipment to the mill, although it takes a large percentage of the yield from their ore to pay for the milling and mining. The Comet is making itself visible with brighter showing than ever. There are several leases on this mine and all the parties are making rich strikes. There are several leases on the Kearsage mine and room for a number or others, as the mine is a good one from one end to the other. The Bailey brothers have realized \$5,000 or \$6,000 within the last few months from the portion they leased, and the prospects are the other lessees will do as well if not better. The owners of the two last-mentioned mines are operating their mines in a most sensible and miner-like manner, by subdividing their claims into portions that can be properly developed by the parties leasing the same, instead of leasing their whole claims to parties who have not the means to properly develop fifty feet of the ground. It is hoped that some day some of the amateur miners holding claims that they are unable to work themselves will see the wisdom of this policy and lease their mines in small lots, thus giving poor men a chance, and enabling ten men to work where there is one at present. It will also greatly increase the value of their properties, if they prove to be worth anything at all after fair trials.

The Gobbler mine has but a small force of men at work, and, although it does not look so well as in the past, yet it may show up in fine shape again. The chloriders on the Silver Odessa are doing well, and it is thought by some that property will again be brought into prominence by rich developments. The Blackfoot has yielded a small fortune to its present owner, and is still looking well. The Sam Houston, No. 3, although it for some time seemed to have been exhausted of the precious metal after Mr. R. B. Johnson realized about \$30,000 out of it, yet on his return the magic touch of his pick revealed another rich deposit and resulted in the sale of the mine to Mr. Chas. Kaufman, who considers that he has a good piece of property, and is developing the mine in good shape with encouraging results. The Cuba, No. 1, is still paying its industrious and wide awake owners handsomely, and will be a good piece of property for chloriding for some time yet to come. The boys can go to Santa Monica and have a royal time and on their return still have a modest bank account to draw from. The Snow Bird after passing through many trials and tribulations is now fairly established as a permanent and paying mine, and with the milling facilities of its own which it soon will enjoy, it will undoubtedly make a record that will astonish the most sanguine. Work is still progressing on the Golconda and the mine is being carefully developed in a small way, but the owners are hopeful of discovering rich leads that will yield each a competency. The Burning Moscow, a fine piece of property, will soon be swelling the weekly bullion reports, and when the law-suit over the Mammoth mine is finally terminated, then that bullion producer will still further augment the silvery stream that is beginning to attract so much attention in mining circles all over the coast. The work on the Mountain Brow is progressing with encouraging results, and a number of chloriders on other claims are delving for the precious metal, mostly with hopeful results. In brief, feelings of hope and encouragement, confidence and positive assurance, imbue the minds of most of the miners and property owners in the district, and the indications are strong that our camp is on the eve of a bright and prosperous future, even though the agricultural districts of our fair State are threatened with drought and short crops.—*Calico Print.*

Belknap, M. T., is made the principal point of debarkation for the Cœur d'Alene mines. A wagon road is completed twelve miles, and will be pushed on to the mines, a distance of 28 miles, and a line of stages put on at once.

USEFUL INFORMATION

Tanning by Electricity.

Making leather is now essentially the same in principle as it was in the days of the Pharaohs. Improvements have been made in the methods of depilating, or removing the hair, from hides and skins, and machinery helps to forward the work in both tanning and finishing, but the aid of a vegetable astringent—tannic acid—is necessary in combination with the gelatine of the hide to make true leather. And this is a long operation, requiring, for sole leather, from four to eight months, and the lighter harness and upper leathers less in proportion. It is now claimed that this long tanning process can be shortened by electricity, and an English patent has been issued with this object. It is well known that hides being "sweated" for unhairing give off a great deal of ammonia, from the combination of the nitrogen of the gelatinous tissue with hydrogen. This process of decomposition is immediately checked when the hides go into the tan liquors, but the precise chemical reactions which take place in the vats have never been clearly understood. In heavy sole leather it is claimed that, in many cases, tannin is deposited by precipitation in the hide cells, besides that which is directly taken up by combination with the gelatine.

The new process proposes to hasten the tanning by enhancing chemical affinity by means of electrical currents, and thus making these reactions more active. The method is to pass a current of electricity through the vats containing the tannin infusion and the hides. The vat becomes simply a large voltmeter, in which gasses are evolved by the decomposition of water—hydrogen at the cathode and oxygen at the anode. The arrangements are such that the hydrogen alone acts upon the hides, where it rapidly combines with the nitrogen of the tissues, and produces decomposition of the gelatinous matters. After a short period, according to the usual manner of changing tan liquors, the solution of tannin is replaced by a more concentrated one, and the current is reversed in direction, so that oxygen is evolved among the hides, where it oxidizes the tannin, and precipitates it in the pores and intercellular spaces in the tissues.—*Scientific American.*

Oiling the Waves.

Wm. J. Card, captain of the coasting schooner Turban, reports some interesting particulars of his use of oil to break the force of waves, on a voyage from North Carolina to Nova Scotia, in September last. The schooner was of 163 tons registered, with a cargo of 300 tons railroad iron, which loaded her down until her gunwales were not more than two feet above water. On the third day out the weather became boisterous, and on the following morning, soon after daybreak, the vessel ran into a gale. The wind was varying about from southeast to northeast, and blew up a heavy sea, the fury of which was increased by a cross sea, caused by the hurricane that had prevailed for some days to the southward of the vessel's position. The schooner, by reason of her deep loading, was completely at the mercy of the seas, which broke over her with terrific force.

Soon after noon Captain Card stationed a man in the bow of the schooner—it being unsafe to venture on the job boom, which was in danger of being carried away by the seas—and directed him to throw over from a small oil can a little oil at the approach of every "comber." The oil was poured out through the spout of the can, and the captain estimates the quantity thrown over each time at rather less than an ordinary tumblerful. As the supply on board was limited, it was thrown out only at the approach of very heavy seas.

At first petroleum burning oil was used, and while this had some effect, it was not heavy enough to thoroughly break the wave, and kerosene oil—some ten gallons of which had been laid in for painting purposes—was then employed. The result was in every way satisfactory, and the use of the oil was continued for about fifteen hours, by which time the supply was exhausted. The fury of the gale had, however, subsided, and the schooner reached port in safety. Captain Card says that without the use of the oil the vessel could not have lived out the gale—the effect of the oil having been to level the comb of the wave and prevent its break in over the vessel.

TWENTY-FOUR O'CLOCK.—Referring to the plan of numbering the hours of the day from one to twenty-four, already partially adopted in some quarters, *Mechanics* says: An examination of some French publications of the fifteenth century discloses the fact that the manner of duplicating and marking the time from 1 to 24, representing the 24 hours of the day, was practiced as long ago as the date mentioned. A notable instance may be found in a work of that period containing a plate of a watch with the hours from 1 to 12 in Roman characters upon the outer rim of the dial, while upon the inner circle the hours from 13 to 24 are arranged in Arabic figures. The dial in question belonged to a watch in the famous collection of Prince Pierre Soltykoff. It was of gold and enamel, and of very elaborate work-

manship. The age of the watch has not been absolutely ascertained, but from certain characteristics of movement it probably dates from about 1547.

THE CREEP OF BELTS.—Why belts creep is owing to the position of the neutral line of bending; the belt is the tightest on one of its sides; there is a difference in the tension of the two stretches that reach from one pulley to the other, and the difference is what is carrying the load thrown upon the belt. This extra tension increases the strain on the outer part of the belt as it passes over the pulleys, and brings the neutral line of bending nearer the face of the pulley, and consequently diminishing the effective diameter of this one, increasing in like manner the other, and giving a result that does not correspond to the figures that have been computed from the dimensions of the pulley and the speed of the shaft.—*Cotton, Wool and Iron.*

A NEW ENAMELLING PROCESS.—A patent has been taken out in Germany for a new process of enamelling ceramic articles. The glass, terra-cotta, stoneware, porcelain or similar article, is covered with a film capable of conducting electricity, by painting the article with a solution of chloride of platinum or nitrate of silver and burning this in, and then decorating as desired with enamel. This is burned in, and the article is afterwards covered electrolytically with the metal. The galvanic coating does not adhere to the enamel, and very varied effects can be produced by gilding, silvering, coloring, polishing, platinizing, etc., the metallic surfaces of the articles.

ORNAMENTAL SHELF PAPER.—In almost any stationery or grocery store in the country "shelf paper" can be obtained. It has scalloped edges and is perforated in prettily arranged designs, making a lace-like appearance. It has grown from a small beginning ten years ago to a large and important industry, requiring expensive machinery and tools to make it. It is estimated that over \$250,000 worth was made and used last year. The paper is run through a press which prints the design, then dies are used to cut the same. The dies are costly.

SAW MILLS.—There are at the present time over 1,500 saw mills in the United States making lumber, but the statement is made by a journal devoted to the lumber interest that there are not now in all of them 100 first-class filers and sawyers, while there are over a thousand millmen who are willing to pay first-class men all they ask for wages.

METAL STRINGS FOR INSTRUMENTS.—Recent experiments with stringed instruments have shown that a much more sonorous tone can be obtained with metal strings than with those now in use, although the labor of playing on them is correspondingly increased. Steel wires plated with silver or copper gave the best results.

It is a curious fact that wasps' nests sometimes take fire, as is supposed, by the chemical action of the wax upon the material of which the nest is composed. Many the fires of unknown origin in hay stacks and farm buildings may thus be accounted for.

GOOD HEALTH.

Deterioration of Sight.

The causes to which this deterioration of eyesight has been attributed, are alleged to be cross lights from opposite windows, light shining directly on the face, insufficient light, small types, and to the position of the desk, forcing the scholar to bend over and bring the eyes too close to the book or writing-paper, etc.

But were all these defects remedied, the integrity of the eye would not be restored nor its deterioration prevented, for there is another great cause of this trouble—the colors of our paper and ink. White paper and black ink are ruining the eyesight of all reading nations. The "rays of the sun," says Lord Bacon, "are reflected by a white body, and are absorbed by a black one." No one dissents from this opinion; but, despite these indications of nature and of philosophy, we print our books and write our letters in direct opposition to the suggestions of optical science.

When we read a book printed in the existing mode we do not see the letters, which, being black, are non-reflective. The shapes reach the retina, but they are not received by a spontaneous, direct action of that organ. The white surface of the paper is reflected, but the letters are detected only by a discriminative effort of the optic nerves. This effort annoys the nerves, and, when long continued, exhausts their susceptibility; the human eye cannot long sustain the broad glare of a white surface without injury. The author of "Spanish Vistas," in Harper's Magazine, says of Cartagena, that "blind people seem to be numerous there; a fact which may be owing to the excessive dazzle of the sunlight and the absence of verdure." Mr. Seward, in his tour around the world, observed that "in Egypt ophthalmia is universal," attributing it to the same "excessive dazzle" of the wide areas of white sand; and the British soldiers in the late campaign in that country

exhibited symptoms of the same disease. In the Smithsonian Report for 1877, it is stated in a paper on "color blindness," that "M. Chevreul has produced 14,420 distinguishable tints of the elementary colors, from which the paper manufacturers could select colors more agreeable to the eye than the dazzling white, so weakening and lacerating to the nerves of that delicate organ."—*Popular Science Monthly.*

VENTILATION OF BEDROOMS.—The necessity for ventilating the bedroom may be made very plain by a simple experiment. Weigh yourself before going to bed, and then again in the morning after rising, and you will find that you have lost from one to two or more pounds in weight. This loss is partly in water; but it is also partly in the carbon of our food—the butter, oil and starch which we ate on the preceding day. These substances have been burned up, and their product carbonized—i. e., with some animal matter has escaped into the air of the bedroom. Now, if a single ounce of cotton were to be burned in the bedroom, it would fill the air with smoke so as to make respiration uncomfortable, and if this were repeated every hour during the night, even then it would not pollute the atmosphere more than the breath of a single individual during the same time. If two persons sleep in a room they pollute the air twice as much as when only one sleeps in the same room. About 3,000 gallons of fresh air should be admitted hourly for each person sleeping in a bedroom, in order to maintain a proper degree of purity. It is not enough to keep the windows open during the daytime; they must also be kept open during the night, or other methods equally efficient employed.

EQUANIMITY AND LONG LIFE.—Will a man live longer by keeping his mind in a state of equanimity? One of our physicians says: "He who strives after a long and pleasant term of life must seek to attain continued equanimity, and carefully avoid everything which too violently taxes his feelings. Nothing more quickly consumes the vigor of life than the violence of the emotions of the mind. We know that anxiety and care can destroy the healthiest body; we know that fright and fear, yes, excess of joy, becomes deadly. They who are naturally cool and of a quiet turn of mind, upon whom nothing can make too powerful an impression, who are not wont to be excited either by great sorrow or great joy, have the best chance of living long and happy after their manner. Preserve, therefore, under all circumstances, a composure of mind which no happiness, no misfortune, can too much disturb. Love nothing too violently; hate nothing too passionately; fear nothing too strongly." No doubt this is in the main correct, but a too quiet life is also unfavorable to the best health.

TO CURE A COLD.—"Feed a cold and starve a fever" is an old adage, and one which most people still believe in. Dr. C. E. Page, however, writes in the *Popular Science Monthly* of an opposite method. He speaks of achieving great success by confining himself to two light meals, or even one meal a day, for the prevention and cure of colds, and has tried it himself in some most remarkable ways, such as "rising from bed on a cold, rainy morning, and sitting naked for an hour, writing, and then put on shirt and trousers only, the shirt almost saturated with rain and the trousers quite damp, from hanging by the window—these and similar experiments I have tried repeatedly without catching cold; I become cold and become warm again, that is all." This may be fun for the Doctor, but we hardly think the amusement of a character likely to become popular. What an enthusiast can do to demonstrate a theory had an even more remarkable exemplification in Dr. Tanner's fasting forty days.

ILLUSIONS.—All persons, even those in good health and of sound mind, are subject at times to illusions. The brain is a very delicately adjusted organ; is easily disturbed in its action by strong emotions, by furious passions, by indulgence in day dreaming or much novel reading or any intoxicating subject which too exclusively absorbs attention. But by keeping the head cool, and by avoiding unhealthy degrees of mental excitement, and devoting our time largely to practical subjects, and keeping the companionship of healthy, well-poised persons, and correcting our illusions by our judgment, we may overcome the evil habit and establish mental health, unless, as is often the case, they arise from diseased states of brain over which the person has no control.—*Herald of Health.*

BRAIN TENSION.—According to the *Lancet*: "Brain tension is not a proof of strength, but of weakness. The knit brow, straining eyes, and fixed attention of the scholar are not tokens of power, but of effort. Tension is friction; and, the moment the toil of a growing brain becomes laborious, it should cease. We are, unfortunately, so accustomed to see brain work done with effort that we have come to associate effort with work, and to regard tension as something tolerable, if not natural. As a matter of fact, no man should ever knit his brows as he thinks, or in any way evince effort as he works. The best brain work is done easily, with a calm spirit, an equitable temper, and in a jaunty mood. All else is the toil of a weak or ill-developed brain straining."

Financial Results of Hydraulic Mining.

The now famous North Bloomfield hydraulic mine, in Nevada county, which has been the figure-head in the debris fight, and is noted for its complete outfit, its large dam, its big artificial lake and its great bullion production, has of course closed down in obedience to the mandates of the courts. The mine has a most complete modern outfit, and used about 3,000 miners' inches of water every 24 hours. It was thought there was from \$35,000,000 to \$40,000,000 of gold left in the channel, but the law prevents this being taken out. The biggest bar of gold ever made was shipped by this company, weighing 511½ pounds Troy, valued at \$114,000. Of the work done at this mine last year, it is scarcely worth while to go into detail, but the results are of great interest. The figures appended give in a condensed form the results. Up to the end of 1882 the company had expended \$2,000,000, including purchase of property. The figures of items of mining cost and water cost are specially interesting to miners:

A New Atlas.	
--------------	--

"Cram's Unrivalled Family Atlas of the World" is the title of a publication we have just received. In addition to the maps of States and countries of the world there are several diagrams giving comparative sizes of countries, their population; area, religion and races, commerce, debt, railroads, telegraphs, etc. There are also elaborate tables of statistics concerning the United States. There are illustrations also, embracing flags of all nations, from all quarters of the globe; principal high buildings; progress of century; prominent species of birds; presidents of the United States; races of men, etc. The maps in this atlas are remarkable for distinctness and clearness, being well printed and colored. In fact, from an artistic point of view, they are exceptionally fine. This atlas has been prepared to meet a demand for a convenient general atlas of the world, at a very low price. It is printed on heavy paper, bound in embossed cloth, with title printed in gold. Size, large quarto, 12x14 inches, and contains 132 pages. It really shows great advance in map publishing, for works of this character are usually much higher in price. It is published by R. A. Tenney, No. 20 Sansome street, San Francisco, and is sold for \$5.

The World's Fair.

An Address to the Public.

To the People of California:—The holding of a "World's Fair" at San Francisco in the year 1887 is the fixed resolve of the people of California. As natural, the city of San Francisco takes the lead in arranging the preliminaries, and calls upon her citizens to take the initiative in what must be regarded as a somewhat ambitious undertaking, and not to be entered upon without due consideration, and when inaugurated to be prosecuted with resolute determination. In order that this enterprise may be successfully carried out, it is proper to say that at the public meetings already held, under the authority of his Excellency, George Stoneman, Governor of California, and presided over by him, there has been appointed an Executive Committee of prominent citizens of the State, who are charged with the details necessary to inaugurate the work intrusted to them. In pursuance of this duty the Executive Committee would have our citizens, and all classes of them within the territorial area to be benefited, fully impressed with the advantages that would accrue from holding a national and international fair in San Francisco. Our geographical position in reference to our own country, as well as toward the Oriental nations, renders this place a most appropriate one for an international exhibition. It will bring together strange peoples, introducing the native races of the Russian, Indian and Chinese empires with the various races that populate the Indian and Pacific oceans, introducing them to American and European families. This is suggestive of a more intelligent and generous feeling than now exists between these different nationalities, aids to break down old traditions and destroy new prejudices, and may be the opening up of more intimate relations and a more friendly intercourse than now exist. By the exhibition of agricultural and mechanical productions it will stimulate not only the commerce that exchanges, but will mutually educate the producers. The arts and industries of the New World will profit by observing the results of the older civilization, while the Old World may be profited by the inventions and enterprising achievements of the younger nations. Our empire of the Pacific, embracing all those States and Territories contiguous to our coast, will reap the benefit of the double observation, and in turn we are afforded the opportunity of presenting the last group of civilized States to the observation of both hemispheres. We need not particularize the advantages to all our business men and men of wealth to arise from a successful "World's Fair." All who are intelligent will appreciate the benefits that will accrue to us from the successful prosecution of this undertaking.

The Executive Committee, to which has been intrusted the inauguration and management of this work, have determined, as necessary to demonstrate the earnestness of our own people in the premises and as a guarantee to ultimate success, and as an evidence of our willingness to show our confidence before we ask the aid of the general, State or municipal government, or before an appeal to the generosity of those beyond our own borders, to obtain a subscription of half a million of dollars, upon conditions which will be more fully made known at the time subscriptions are solicited by the Finance Committee, which will be organized and enter upon active duty in the premises on Monday, March 3, 1884.

All of which is respectfully submitted.

WASHINGTON BARTLETT,
Mayor of San Francisco.

T. H. GOODMAN,
GEORGE STONEMAN,
M. D. BORUCK, Governor of California,
Secretary. President.

THE San Bernardino Times says the freight charges on ore from Calico to Pueblo, Col., is \$25 per ton, against \$6.52 to San Francisco, yet the miners get better returns from the former after paying the additional freight. Why this is so should be investigated and a remedy applied that will keep the business of ore reduction within the borders of California.

At the annual meeting of Wells, Fargo & Co., in Denver, the following were elected: President, Lloyd Tevis; Vice President, General Manager John J. Valentine; Secretary, James Heron; Treasurer, Henry Wadsworth; Directors

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

DOYLE.—Amador Ledger, Feb. 9: Daniel H. Sawyer, who purchased this promising claim in Hunt's gulch a few months ago, and immediately thereafter started East for the purpose of organizing a company to develop it, writes to us from Scowhegan, Maine, under date of January 27th, in the following encouraging terms: "I wish to say to you and friends in Jackson that my journey East has been completely successful. I have made arrangements with a wealthy company to take stock in the Doyle claim. I can give you the best assurance that inside of a year we shall have a 40-stamp mill running on that claim. My company will be composed of men of experience—old Colorado and New Mexico miners. I shall soon return to Jackson, and hope to do something to develop the mines in that section."

VOLCANO NEWS.—Amador Dispatch, Feb. 9: This last rain has helped the mining interests considerably, as no gravel mines were worked up to the present owing to want of water, and very few of the quartz mines. Rich rock has been found in the Downs mine in the south shaft. The ledge is five feet wide, and pays ten dollars to the ton. They cleaned up from \$7,000 to \$8,000 from ten stamps. They are now running twenty stamps day and night. Gillick & Phillips are taking out rich rock, and it continues to improve as they go down. The Tunnel Co. is running day and night as long as this water lasts. The St. Julian mine, which commenced a few weeks ago to make itself notorious by producing rock of almost unequal richness, is not only "holding its own" in this respect, but continues to produce more and more of it, and of a richer quality than at first. The last lot of ore brought up was completely studded with large specks and chunks of gold of various sizes. It would require only a few tons of such rock to make all its owners independently rich. They are developing the mine as rapidly as possible, and it is to be hoped that the rich strike will not soon "peter out."

MISCELLANEOUS.—The owners of the St. Julian prepared to the mine in the early part of the week, and in the course of a few hours took out from the floor of the tunnel a quantity of rich quartz, estimated to contain several hundred dollars in free gold. The development of the mine is pretty much at a standstill just now. The ore streak seems to be mainly below the tunnel, and to get in out it will be necessary to sink a winze, and open up another level, involving considerable time and expense. The heavy rains have washed out the small gulches thoroughly, and prospectors are out in force searching the bedrock for gold. Parties have made as high as \$5 in a few hours by simply panning out. A new ore chimney has been encountered in the Downs mine at Volcano, of high grade, and sufficient, it is claimed, to keep the mill running for a couple of years.

Calaveras.

SOUTHERN MINING JOBS.—Angels Echo, Feb. 6: The Reserve mill is kept steadily going and pays well. The Invincible mine is paying well and the vein is 20 ft wide. Taylor & Co. are engaged in erecting two nine foot arastras on their mine near his town. Both mills at Carsons are running steadily which is a pretty good indication that the ore is paying. We understand that preparations are making for the erection of a 20 stamp mill on the Mar- bal mine. The new 10-stamp mill on the Morgan has been running about a week and works well. It crushes an average of 21 tons of ore in 24 hours. F. Johnson & Co. recently sold their quartz mine, situated near the town to a San Francisco party who intends to commence working the mine as soon as convenient. Mr. Chas. Smith, Supt. of the Fair Play mine, has been placed in charge of the new enterprise. The price paid for the mine has not been made public.

El Dorado.

ETNA MINE.—Cor. Mountain-Democrat, Feb. 9: here is some excitement here at present about the Etna mine starting to work again. This mine is six miles west of Fairplay on Grizzly Gulch, in Cosmes township. It was discovered and located by A. C. Hite in 1876, and was formerly known as the Little sulphuret mine. He worked it to a depth of 80 ft., and 60 ft in length. The ledge was from 3 to 10 wide and he took out about \$1,700, by running the ledge matter through sluice-boxes, obtaining the free gold and saving the sulphurets with an old tom ton, and sending them to the works at Drytown, Amador county, which paid him a handsome profit. The mine was worked two years by Hite. It has since been owned and worked by a corporation known as the Etna G. M. Co. This company built a fine 20 stamp mill, erected hoisting works, and took out considerable money, but owing to bad management the company made a failure and suspended work, and by one process of law the property came into the hands of Mr. A. J. Burnett of Oakland, a man of real mining experience, who has associated himself with a corporation to be known as the El Capitan G. M. Co., its directors being Chas. S. Bradford, G. E. Buckman, Carl Strohle and James M. Day, and ere long the old Etna will resume work. D. C. Hite, the original discoverer and locator, has not quit mining nor has he left Etna for good. He wends the extension of the Etna on the north, the ledge that was formerly known as the Moco, but at present the Golden Eagle. This mine has been worked to some extent with satisfactory results, and bids fair to be a good mine. I am credibly informed that Mr. Hite has been offered \$1,200 for a fourth interest.

EUREKA MINE.—Georgetown Gazette, Feb. 8: The Eureka mill has been supplied with Hendy concentrators this week. The Tasker concentrators, manufactured at Philadelphia, after a thorough and expensive trial, with both the defunct Tasker pulverizer and the new ten-stamp mill, proved a failure: the mill, concentrators, pans, etc., are all manufactured in California, and Supt. Powning is now happy, and will work the ore for all there is in it. Just before the late storm the water fell a little short owing to freezing weather in the mountains above, then a cleanup was made from about 180 tons of

ore. The result was even more than expected. Had the Hendy concentrators been in place, and the sulphurets properly cleaned and saved for the pans, the result would have been even better. This result, in the words of the Supt., insures the early addition of ten more stamps. All who saw the large amount of amalgam and the large ingot of gold resulting therefrom, are united in proclaiming Eureka a success. For good reasons the Supt. is not permitted to make public the result.

Inyo.

THE MAGNET MINE.—Inyo Independent, Feb. 9: The Magnet mine, situated in the Telescope Range, south of Panamint, and owned by Spear & Thompson, is showing up finely. Considerable work has been done since November last, and the present prospect is that it will turn out to be a productive property.

CHLORIDERS.—The chloriders are all busily at work in Russ and Union districts, and we are informed are taking out rich ore.

DAKWIN.—Flattering reports are received here daily from this mining district, and if what is said is reliable (and we have no reason for doubt), in a short time the old camp will spring into new life and give its inhabitants a taste of the good old times of yore. The rich strike in the Defiance, together, with the pushing of work on other mines there, is attracting attention from all quarters.

ELNA FURNACE.—This furnace is again in full blast. They have on hand a lot of ore from the Farrington mine, Garfield district, Esmeralda county, besides a quantity from their own mine, which will keep the furnace running steadily for some time. The last cleanup showed that the ore worked yielded \$1,600 per ton! How is that for Inyo county?

THE ARGUS RANGE Silver Mining Company, at Reilly, Sherman district, shipped to San Francisco, last Thursday, six bars of bullion, valued at \$7,000. The third shipment within about six weeks, from the Brown Monster mine, Russ district, of 11 tons of ore, rich in silver and gold, will go forward to San Francisco to-day. The Furnace at Swansea has just received a thorough overhauling, and will be put in motion again in a few days. A. W. Eibeschütz will soon put men to work on the Potosi tunnel, Cerro Gordo district, to take out the rich ore struck there for shipment below. Men are at work in all the surrounding districts, and lively times are expected in Inyo county the coming summer.

THE MAXIM M. & Co.—The Maxim Mill and Mining Company, whose pulverizer was wrecked recently during the first 24 hours run, have decided to replace the broken part with new, and give it another and thorough trial. The builder has, it is stated, secured the friction plates, this time obviating any danger of displacement, so that the ordinary wear of the machine is the only question to be decided. The balance of the plant is first-class, the ore easily crushed, the management competent and careful, and the merits of this grinder, if it has any, will now soon be demonstrated. The new portions of this mill are already on the way here by express.

Mono.

BODIE MINE.—Free Press, Feb. 6: There is a visible improvement "all along the line," with good promise of something better to come. While we are not over-sanguine, we believe that this district will make quite as good a showing during the coming season as it ever has. Certainly, the outlook could not be brighter nor the condition of things healthier than at present. What we have in sight we are certain of—the rest we hope for, with solid evidences of realization. Take it all in all, the mining prospects of Bodie are better than good.

STANDARD CON.—During the past week there were extracted and sent to the mills 1,386 tons of ore; 1,315 ounces of crude bullion were received, and \$10,853 shipped to the company. The winze from south drift No. 2, 385 level, is down 83 ft; progress 11 ft. The vein is four and a half ft wide of good ore. The stopes are looking as well as usual, and everything around the mine and mills is running smoothly.

BODIE CON.—Supt. Irwin reports as follows for the past week: The usual quantity of ore was shipped to the mill. The ore was extracted from the 200, 306, 600 and 780 levels. Upraise No. 1, 306 level, has reached the height of 73 ft. The vein at this point has widened to about four ft of very rich ore. The north drift, 550 level, is in 77 ft, with about one foot of good ore in the face. We have been preparing during the week to extract ore from the 306 and 200 levels, and now have ore ready to ship to the mill from these places.

BODIE TUNNEL.—The ore formation in the stopes both north and south on the 300 level is looking well, the ledge averaging about three ft in width.

GOODSHAW.—Owing to the late storm they were unable to start up the works, but as soon as the roads are passable and water can be obtained to fill the tanks, they will start up.

MATTERS AT BENTON.—Cor. Bodie Free Press, Feb. 9: Work still continues at the Wild Rose, but the snow will prevent hauling ore to the Banner mill for some time, though there is enough ore delivered to keep the mill running for six weeks or more. Encouraging reports come in from those prospecting in the White Peak or old Montgomery district, and the chances are that next spring will show up some new developments. The Diana mill has just closed a short and successful run on a lot of ores from various mines in the vicinity of Benton, and demonstrates the possibility of working our low grade ores to good advantage.

Nevada.

MAGENTA MINE.—Grass Valley Union, Feb. 6: Some rich specimen rock has been taken out of shaft No. 5, on the ledge within the past two days, at the depth of thirty feet. This rock, it is estimated, will go fully \$150 per ton, and it will do that and more to judge from some of the specimens taken out. A new eight and a half inch pump has been put in the Magenta shaft down to the 300 level, to replace the six inch pump, and a seven inch from that to the 400 level, and the water is now handled without difficulty. In making the change the water increased somewhat in the shaft, but it is being disposed of rapidly, and the sinking of the shaft and the drifting on the 400 level, which has been interrupted for the past week will be immediately resumed.

MINING IMPROVEMENTS TO BE MADE.—Grass Valley Union, Feb. 6: The Nevada G. and S. M. Co. is negotiating for heavy machinery to work their

mine on Ophir hill. The Company has also bonded the Peabody mine, and the Grass Valley Mining Company's claim on New York Hill, better known as the old Bobby Smith ground. Work is to be commenced on all of these claims immediately. At an early date the Company will also erect a 10-stamp mill, with all the modern improvements, a mill-site having already been secured near Boston Ravine.

LEAVING THE HYDRAULIC MINING SECTION.—San Juan Times, Feb. 9: A number of the residents of Columbia Hill have gone or will soon leave to seek homes elsewhere. Some will go to the southern portion of the State, or to Oregon and Washington, to make future homes for their families. Since the Sawyer decision the people in this part of the county are all at sea, and the disposition to emigrate is strong among them. Unless something turns up to turn the tide of emigration to the Ridge (the country between the South and Middle Yubas) will be nearly depopulated before another year rolls around.

WATER POWER STARTED.—Nevada Transcript, Feb. 12: The Charron Company have turned on the water power at their mine, and the pumps are now run by that cheap and convenient motor, which is also to do the hoisting very soon. The connections were also made with the mill, but some of the gearing broke after a short run, and steam had to be started in that department again while the necessary changes and repairs are being made. In a few days the water will be doing all the work out there that has heretofore been done by steam engines.

DULL TIMES AT SMARTSVILLE.—Grass Valley Union, Feb. 12: Through injunctions and legal obstructions of various kinds, all of the mines at Smartsville are shut down, and in consequence the times are very dull there, and it is feared there is little hopes for improvements. Many of the unmarried men have gone away, and a number of the married have also sought other locations to obtain employment, with a view to removing their families. Among those remaining there is a strong disposition to seek the new mining fields in the Coeur d'Alene region, and with the coming of spring it is the intention of quite a number to emigrate there, in the hope of finding new diggings and a new home. This is one of the effects of shutting down the hydraulic mines, and Smartsville is not the only mining locality that will be to a large extent depopulated from this cause.

LOCAL MINES.—Tidings, Feb. 5: The Idaho Co. have their ditch clear, and work was resumed underground on Monday, after a delay of three or four days. The ledge in the lower level is very large and rich, much more so than usual with the large veins found in this famous mine. On Monday the Idaho Company declared their 171st dividend, this time amounting to \$5 per share on the capital stock. The Empire (the oldest mine in the district) is looking better than ever, and is turning out rich ore,—the ore now coming out showing sulphurets and gold freely. The 20-stamp mill at the Empire is kept running day and night. There has been a great change in the appearance, underground, at the New York Hill mine. For years past the rock has been extremely hard and progress in driving drifts was necessarily slow. Three and one-half ft per week has been about as much as the miners could drive in the drifts. Week before last the distance driven in the 13-level was nine ft and last week it was 12 ft. The ore looks much better than it has for a long time. The Slate Ledge Quartz M. Co. are meeting with success. The company are only prospecting, and there are only two or three owners. Since May last something in the neighborhood of \$7,000 has been taken from this claim and last month a dividend of \$600 was declared. The contractors who have been sinking the shaft 50 ft deeper at the Imperial mine, have completed their work, and another contract has been let for sinking 50 ft further. The ledge is looking well in the bottom, and is gradually improving as depth is attained. The North Banner Con. Tunnel Co. are getting out very good ore, and the mill is running night and day. The company have made arrangements with J. M. Lakeman for putting five additional stamps in the mill. The company have considerable rock on the dump which is being put through the mill as fast as possible.

Plumas.

SPANISH RANCH.—Cor. Plumas National, Feb. 12: "The Thompson & Kellogg bed-rock tunnel is into the Wahponsee mountain over 200 ft, and it has cut heavy springs of water lately. The workmen are daily expected to strike the back channel known to be in the mountain. John O'Brien is still working his old claim on the Wahponsee—very quiet, but he "gets it, all the same." Challen & Co., in the Sharp Ravine diggings, are still pegging away into the mountain, expecting every day to strike it big. Abe Bolyar, on the Queen Sabe, is reported doing well. S. S. Taylor, in the McVey diggings, is putting up one of the new patent hydraulic elevators, and will make his claim "shell out" in good shape this spring.

Shasta.

SOUTH FORK.—Shasta Courier, Feb. 9: The mining items from South Fork are somewhat scarce at present, as only 3 of the 5 arastras are running, though about the usual amount of work is being done on the mines. The erection next Spring of the two Cannon Ball mills, now contemplated, and the rumored starting of the old Peck—now Willard—mill, will add materially to the growth of our camp. O. Engle and H. Dunham have commenced piping in Kanaka, opposite Muletown, and are sanguine of success. Two giants are now at work in Hard-scrabble.

NEVADA.

Washoe District

SIERRA NEVADA.—Virginia Enterprise, Feb. 9: Connection between the 2000 and 2700 levels is about made. This connection will give a circulation of air that will permit of active prospecting in the north end of the mine. The northeast drift on the 3100 level is being rapidly advanced. The face is in quartz, with one streak that prospects well in gold.

OPHIR.—The usual progress is being made in the drifts on the 150 level. These drifts are finding some streaks of ore.

UNION CON.—The main north and main south drift on the 3,100 level will connect about next Monday or Tuesday. This connection will give a circulation of air that will cool off all the lower levels and permit of active prospecting in all directions.

ALTA.—There has been some delay in the work of

advancing the east crosscut on the 2150 level, owing to deficient ventilation, but this has been remedied, and the work will now progress regularly and rapidly.

HALE AND NORCROSS.—The sump below the 2800 level has been completed, and a station is being opened at the 2800 level, from which exploring drifts will be run. The rock is of a very favorable appearance.

BEST AND BELCHER.—The material at the bottom of the joint Gould and Curry winze, down from the 2500 level, remains about the same. There is some water, but it does not greatly interfere with sinking.

COMBINATION SHAFT.—The shaft is nearing the 2800 level, at which point a station will be made and a drift started west. The shaft will be put down to the 3000 level as soon as possible.

UTAH.—The northeast drift on the 1750 level is now out about 250 ft. The face is in a favorable vein material carrying quartz that gives promising assays.

BELCHER.—The regular amount of ore is being extracted from the old upper levels, and the mills on the Carson river are again running to their full capacity.

SAVAGE.—Good progress is being made in the exploring drifts to the northward on the 2600 level, and the ground presents a very promising appearance.

IMPERIAL.—The main west drift has now entered the regions of the old upper levels in which it is expected to find a considerable quantity of milling ore.

MEXICAN.—The mine is being thoroughly overhauled and put in good repair from the 2500 down to the 3100 level preparatory to active prospecting.

YELLOW JACKET.—A full force of men is now employed in the mine, as there is a good stage of water in the Carson river, and the mills are all running.

SCORPION.—The face of the main west drift on the 500 level is in vein porphyry, with occasional streaks of quartz and clay.

CROWN POINT.—The mills on the river being now able to run to their full capacity, operations are again active in the mine.

ANDES.—A good deal of quartz of good quality is being found in the drifts, with some ore that will pay for milling.

Columbus District.

THE COLUMBUS CON.—True Fissure, Feb. 6: The main shaft has attained a depth of about 90 ft below the station of the third level, making a total depth of about 340 ft. The ground in the bottom of the shaft is somewhat mineralized, and favorable for good progress in sinking. The drift from the shaft on the third level has reached a length of about 65 ft. Up to a few days past the ground in this drift has been very hard, when it suddenly changed to a very favorable nature for working. There is a small seam of quartz in the face that gives low assays. The drift from the bottom of the Bonanza winze has attained a length of about 115 ft, and it still continues in broken up vein matter. There remains about 42 ft of a drift to run before connecting the bottom of the Bonanza winze with the shaft on the third level. The south crosscut, from the lateral drift on the 150-foot level, has been discontinued, and drifting commenced on the ledge encountered in running the crosscut. It is expected that the fourth level station will be cut out during the coming week, and after it is completed the work of drifting towards the ledge will be commenced immediately.

Como District.

AN ISOLATED COMMUNITY.—Virginia Enterprise, Feb. 9: The people of Como are now as a community about as solitary as though they were planted on Pitcairn's Island or a patch of ground far out in the midst of the ocean. The mountains rise up about them as white and glittering as so many icebergs. If they are having a good time they are having it all to themselves. They all deserve to become millionaires, for many years have they toiled up there in the lone mountain.

Eureka District.

LOCAL NOTES.—Sentinel, Feb. 10: The Home Ticket grade is again full of snow. Prospects in the Connolly mine are improving daily. The indications for ore in the Mildred mine at Secret Canyon are very good. Report has it that the lessees of the Wittenberg & Hamilton mines have struck it rich. The Silver Connor mine is still producing good ore, but the heavy snow storms prevent shipments. The Jones brothers are shipping some very fine ore to the Richmond furnaces from the Queen mine at Silverado. The Silver Nugget mine at Silverado will be leased as soon as the drifting snow will permit miners to examine the ground. Charley Bro's teams have been busily engaged during the last week hauling ore to the furnaces from the Silver Lick mine on Adams Hill. Some good ore is being extracted from the El Dorado No. 2 mine, on Prospect Mountain, which, as soon as the weather permits, will be shipped to the furnaces. Charley Graham and H. B. McKee, who have been working the old Page & Corwin mine under lease, are now in splendid looking ground for ore. They have been running a drift from the old works, and are in an iron formation with a talc foot-wall, which, in that section, means "ore near by."

Pioche District.

TAILINGS.—Pioche Record, Feb. 2: It seems that the three parties concentrating the Raymond & Ely tailings at Bullionville are doing very well. They have about fourteen tons of very fair concentrations ready for shipment to Salt Lake, that will net them some \$600 clear of expenses. This is the result of two months labor. In case the Bullionville Smelting Company should ever want to start up their furnace again, they will have to put in a new crucible, as the old one is completely demolished, parties having torn it up in their search for bullion.

Schroder District.

THE NEW CAMP.—Cor. Eureka Sentinel, Feb. 10: This new district is 10 miles north of Carlin. A good many people have visited this camp, and have staked off claims in the snow. They could not prospect much as there is very little bare ground to be seen. There are only three mines that are trying to work any this winter. The Grace Darling has four men on; the Yankee Doodle, 4; and the Comstock, 6. They are all taking out ore. Not enough work has been done on any of them to give much of an idea as to what they may amount to, or the extent of the ore deposits. The appearance of the Grace Darling and Yankee Doodle mines is not that of a

defined ledge. They each seem to have a mass of ore from 100 to 150 ft across each way, and they are sinking each one a shaft in the center of the mass. The ore is of various characters. It contains chloride, carbonate and oxide. It assays from \$700 to \$1,000 in silver per ton, with very little gold; and from 10 to 20 per cent of lead, and 1 to 2 per cent of copper. The Grace Darling has a shaft down 15 ft, and has over 500 sacks of ore sewed up ready to ship. In the bottom of their shaft the ore has become more solid than it was on top. The boys call it beeswax ore as it resembles beeswax ore very much, only being much heavier. The Yankee Doodle is down 6 ft. They have the same quality of ore as the Grace Darling. Their shaft is 600 ft northwest of the Grace Darling shaft.

ARIZONA.

NOTES.—Prescott *Courier*, Feb. 4: Mr. W. C. Dawes, who has just returned from the Tipton county, visited mines in Bradshaw, Peck and other districts, and is pleased with the outlook. Smithline and other miners are doing well in Humboldt district. Judge McPhee is developing a promising ledge near Bumble Bee station. E. S. Junior and his brother miners of Bradshaw district, have huge piles of rich ore at their shafts and tunnels. The Black Warrior mine is yielding good ore, which is being milled. Rich rock was recently struck in the Peck. Mr. Dawes heard that the Senator and Groom creek mills were running. The gentlemen who came from New York city with Mr. J. S. Alexander experienced rough weather in our mountains, but expressed themselves pleased with the mines, the country and with Mr. T. J. Eaman's management of their mine and mill. S. C. Miller and others are taking rich ore from a large mine near Kirkland valley. They ship the ore to Benson. The Copper mountain smelter is to start to-day. United Verde is running. Parties of miners from portions of Nevada, Utah, New Mexico and Colorado are arriving here, en route to Quijota. They will go by Phenix and Maricopa, which is the shortest and best route.

STAY AWAY FROM QUIJOTA.—Tombstone *Epitaph*, Feb. 9: There is not a better mining man on the Pacific coast than W. H. Patton, or as he is more familiarly known by the old Comstock miners, Billy Patton. He is now the General Supt. of the properties in the Quijotas recently purchased by the bonanza firm. In the course of an interview with a reporter the Tucson *Citizen* he made the following statement, which it will be seen corresponds in every essential particular with the opinions expressed by Mr. E. Schieffelin, and recently published: What work is now going on in the Quijota mines? We are driving three tunnels, one on the Logan side, and two on the other. The distance is so great that all the miners have to camp right at the tunnels. There are eight men at work on each tunnel. They are being made by contract. That is all we have at present employed. The tunnel will not need to be timbered, as in the Comstock; the rock will hold itself. How many men will you eventually employ? That depends upon the capacity of the mine. We must first get in our tunnels, winzes and upraises. Then if we have the capacity, that is if we find the ore bodies we expect, we shall then be able to employ a large force of labor, but this is yet quite away in the future. We shall first have to find water, and do our preliminary work in the mine before we can employ miners. People are rushing there altogether in too great haste. It is too bad to see good men going there without a cent. They will certainly see hard times. I wish you newspaper men would discourage as much as possible the untimely rush. People think because of the names of the men who have bought the mines that times will necessarily be good. But they are deceived. There will be plenty of time to go there after water shall have been discovered, and the preliminary tunneling done. But I suppose people will go, although there may be a few sensible enough to profit by the newspaper advice, and go slow.

COLORADO.

QUEEN OF THE WEST LODE.—Colorado *Miner*, Feb. 6: We learn from a Decatur party that, in driving the main drift on the Queen of the West lode, in the Horseshoe, quite a large streak of high grade mineral has been encountered. The mine is owned by a Rochester company.

THE SHIVELY.—Very encouraging reports come to us from this property. It is situated on Brown mountain. Messrs. John Frazier and John Johnson, who are leasing on the 75 and 145 levels, are enjoying excellent pay at present. As the work of exploration goes on there is a noticeable improvement in the pay streak. The mineral is a sulphuret and will range from 300 to 700 ounces silver per ton.

AN IMPORTANT STRIKE.—What is destined to be a very rich strike of mineral was made in the Home-stake tunnel, on Red Elephant mountain, a short distance above Lawson, last Tuesday. The ore is scattered throughout the eighteen inches, and ten inches of solid ore. The miners pronounce the ore exactly as that of the White, and will average from 300 to 400 ounces silver per ton. In two days time two tons of ore were extracted and sent to the Stephens' works.

CORRY CITY.—The machinery is all in place, and is now being adjusted by the constructors. There remain 70 ft in depth of still rock in the lower part of the new shaft to be hoisted. As soon as this rock is removed the lower portion of the shaft will be cribbed and a skip track laid therein, in like manner as above crosscut tunnel level, thereby making direct connections from surface to bottom of new shaft. The ore in the mine is improving in quantity and quality as depth is gained. Some of the features of handling are that the skip will work automatically, dumping itself into a shoot, to be immediately constructed, connecting the top of the shaft with the ore house. In this shoot there will be two screens with large receiving pans below, in which will be caught the fine ore as it passes over, the coarser blocks or pieces descending to the ore house for cobbing. This, it is thought, will effect a considerable saving.

EMPIRE.—From present indications there is a genuine boom in store for the mines of this camp. The Bay State mill, situated a short distance north of town, is now running in full blast, under the management of Nieman & Co. It has 16 stamps and will be used for treating the ore from the Crown Prince and Prince Albert lodes. These mines are

being extensively developed, with flattering results. Large quantities of excellent mineral are being taken out. Messrs. Fletcher & Barrett will start up their Knickerbocker mill the coming week. The celebrated Tenth Legion mine will supply the ore. This mine has large ore reserves which are untouched as yet.

THE DIVES AND PELICAN.—During the week our reporter visited this famous property, which more than any other, has given Clear Creek county her reputation as a bullion producer. Probably no mine in the county is so extensively opened up as the Dives and Pelican group, one of the drifts alone being 1,300 ft in length, and several others five and six hundred ft each, all of which were traversed, and showed an excellent state of repair. The main shaft is now down 1,015 ft, but work on it has been temporarily suspended. We cannot assert with any certainty what the mine is at present yielding, but vast bodies of low grade ore are exposed in various places, which Manager Duff informed us could be profitably worked were it not for the excessive freight charges (\$7.50 per ton) necessary to market the same. Fifty-eight men are working the mine. Lessees on the 340 level are sinking a winze on the Unicorn lode and are now down about 25 ft. Silene & Co. are stopping up from the 340 level on the Pelican lode, about 400 ft from the main shaft; and they now have in their stope in place two ft of solid mineral of about the same character as that found in the Unicorn. That this property will one day resume its former proud position cannot much be doubted, but aside from the work done by the lessees, so long as present exorbitant freight and mill charges continue, the work done by the company will be done with a view to make permanent improvements for future operations, when the vast ore reserves in the mine can be taken down and banded profitably.

DUMONT.—Miners' wages have been reduced at the Albro mine here to \$2.50 per day. This reduction creates a great deal of dissatisfaction among the men.

IDAHO.

A BIG SLIDE.—Ketchum *Keystone*, Feb. 9: A tremendous snow-slide occurred on the mountain overhanging the Queen of the Mountains mine on Wednesday last, which descended with a grand sweep over said works. The shaft was filled with snow, and everything on the surface covered up entirely by snow which followed in the "wake." The mountain is a very high and steep one, and had the owners of said mine concluded to work it during the winter their houses and other property, together with their lives would have been destroyed.

NO HURRY.—Coeur d'Alene *Miner*, January 26: Another private letter says that the mines are more extensive than the public are aware of. That those intending to go need not be in any hurry, for it can not possibly all be taken, even in the next year. The snow is now very deep, and the trails and roads next to impassable. Those there now can do little or nothing until the snow is off. Snow fell here last week to the depth of ten feet. Provisions are high and scarce. Another item in the same paper is as follows: Forty-five miles northeast of Pritchard creek a new gulch discovery has been made, in a valley about one and a quarter miles wide and fifteen miles long. It is reported richer than the placers on Pritchard or Eagle creeks. Digging through seven feet of snow, prospectors discovered diggings going \$1.25 to the pan. A rush has already set in.

COEUR D'ALENE LODES.—Cor. Salt Lake *Tribune*, Feb. 8: There has been development enough on the creek as yet to pronounce the camp a big thing, although there are good prospects in placers on the high rock. There are also several lodes that are very promising, the mother lode in particular. I have seen five ounces of gold pounded out of a piece of rock from that ledge. I have been inspecting the same lode; it shows on croppings very rich coarse gold that would weigh \$2 or \$3, but it is too much of a specimen rock or ledge to suit my ideas for a big mine. I have located two lodes in the camp that look very promising. They are in quartzite formation, but there is so much snow on the ground that it is impossible to trace anything. What I have seen of the camp is very encouraging. The bed rock is slate formation most invariably on Pritchard Creek. The gold is very coarse and well washed. The side gulches emptying into the main creek have a different character of gold. It is more rusty or oxydized. The side gulches do not prospect much and not over half a mile from the mouth. My opinion is that there is an old river running parallel with the main creek through the divide. I shall hunt it up as soon as the spring opens. There are some fellows who became discouraged with the camp and left it, cursing the country. Another correspondent of the same paper had an interview with T. S. Merchant, who has just returned from the new mines. There are about 800 men in Trout Creek Station, about 300 on the trail from that place to Eagle City, and probably about 600 in the mines. There are some individual instances of absolute distress. Men coming from a clime far different from this northern country, ill provided with serviceable clothing, and with inadequate means, are suffering; and as there has not yet been found sufficient prospects to justify such a stampede, it is the opinion of Mr. Merchant that it is the duty of humanitarian journals to counsel a halt until the season of the year arrives that they can camp out doors with less danger of life and suffering. Lots at Eagle City are selling at from \$200 to \$500. The men going in from Trout Creek have established stations four or five miles apart, and a constant fire is kept burning, one party leaving kindling for the party behind, and the half-cold fellows are kept alive. Many people going into Eagle City have trained dogs to harness, which are extensively used in pulling their toboggans. They haul about 150 pounds. Mr. Merchant, in his observations, takes in the fact that sheet iron makes the very best toboggan that can be used in the transportation of supplies, etc. over the narrow trail between Trout Creek store and Eagle City. Nails are worth about \$9 per keg at Trout and \$30 at Eagle. Hence a few enterprising persons are making money by the toboggan express. I asked the gentleman if there was not a heap of smoke for the fire that had been kindled. He immediately said there was a great deal of smoke, yet there was no fire kindled, and he deplored the fact of such a rush being created towards the Coeur d'Alene without a more cogent reason.

THE NEW PLACERS.—Coeur d'Alene *Miner*, Feb.

6: A Stage and Freight Company at Spokane Falls, will start a stage and freight line to the mines this week. The fare will be under \$10, and the freight six cents. Stages will make the trip from the Falls to the mines in 24 hours. Several pack trains are running from Spokane Falls to Eagle city, the principal settlement in the mines. Snow is five ft deep in the mines, and will not go off until April or May. People at the mines and at the Falls talk about an immigration in the spring of from 50,000 to 150,000. Several new towns will be laid out in the mines in the spring. Men talk about an abundance of gold in every gulch in the mountains. It is said, Eagle city will have 10,000 people by the first of July. It is intimated that every one need not expect to make a fortune the first season. Provisions are high at the mines, and no one has any business there unless he has a pocket full of money, and a large stock of grub and a place to put it in. It has been snowing at the mines two weeks and all the trails are impassable. "A dozen of Summit valley miners from Montana, have discovered a quartz ledge 30 miles north-east from Eagle city, and traced the croppings three miles. Assays of the ledge show \$482 per ton. This is white crystallized quartz."

Men are busy all around, although not much work is being done on the mines. Men chopping wood earn from \$7 to \$8 a day, and building is quite expensive. Ax handles sell for \$2 apiece; coal oil \$18 a gallon, and Mr. Knapp says he saw two men fighting over the ownership of an old tin oil can, which each wanted to use as a water bucket. Flour sells at \$40 a barrel, and everything in proportion. Lots sell from \$50 to \$600, depending upon location. Mr. Knapp's impression of the camp is a very favorable one, but he thinks that it is too early to go in just yet, as prospecting is almost impossible with five feet of snow now on the ground. He thinks the quartz mines will prove better than the placer claims and that more quartz claims than placers will eventually be located. He thinks the prospects are good for a permanent quartz camp. Most if not all of the placer claims have been taken up in claims of 20 acres each. On the 10th of this month, next Sunday, the miners intend holding a meeting to cut down the size of the claim and to adjust the amount of land that each man will be entitled to hold. The meeting will also decide how many town lots any one man can hold, and will make some condition necessary for a man to maintain title to his land, such as erecting buildings within a certain time, etc. The placer claims will probably be cut down to five or ten acres in extent, and no one man will be allowed to hold 20 acres in his individual name. A new Recorder will also be elected, as great dissatisfaction is being expressed with the present incumbent. Trouble may arise from any attempt to subdivide the claims already staked out, and lively times are anticipated.

MONTANA.

THE ANACONDA *Inter-Mountain*, Feb. 6: For the 20 days ending yesterday the Anaconda company shipped 2620 tons of crude copper ore. This month and monthly hereafter the shipments of the company will aggregate 25,000 tons. The amount of ore now being raised from the mines is 14,000 tons per month. Over 200,000 tons of ore are on the dump. This is all workable ore and will be shipped to the smelter on the completion of the Anaconda branches. The smelter will start up in September. The concentrator will have a capacity of 500 tons per day and additions will be made to the capacity of the works until they will be able to treat 1,000 tons of ore every twenty-four hours additional to that which will be shipped in a crude state. The smelter will consume 50 tons of coal and 30 tons of coke per day. The matte shipments to Europe will exceed 100 tons daily. The shipments to the mine will consist principally of timber, of which 12,000,000 ft a year will be consumed. The daily ore production of the mine will be 1,000 tons and the company will probably give employment to 1,200 men all told. When the Anaconda smelter shall be in full blast, and if the other copper companies of Butte maintain their present output, which they are quite certain to do, the shipments of Butte in 1885 will exceed those of all other towns on the line of the Northern Pacific from St. Paul to Portland.

ANACONDA.—*Inter-Mountain*, Feb. 4: In the year 1885 and thereafter indefinitely, the Anaconda Company will ship from its smelter in the Deer Lodge valley over 100 tons of matter daily, and when it shall be completed according to the present specifications, its outgoing tonnage will be still further increased. The company's operations will be conducted on a scale never before equalled on the Pacific coast. The mine will be called upon for a daily contribution of 1,000 tons of ore, every pound of which will be sent to the smelter for treatment. So extensive will be the development of the mine, that 12,000,000 ft of timbers will be annually used to support the roofs and sides of the subterranean caverns, which will be excavated in the extraction of ore. The company will, in 1885, when the smelter is in full blast, handle more ore than all the mills and smelters of Butte treated in 1883. The output of the camp will be almost doubled. Yet it must not be supposed that the other smelting companies of this district will be idle. It is announced that the capacity of the Montana smelter, which is now 100 tons daily, will be doubled in the near future, and that plans and specifications for the work are now being prepared. The capacity of the Colorado smelter is also being enlarged. With only four stacks it was totally inadequate to treat the vast available supply of ore. The Parrot smelter, with a magnificent mine to keep the furnaces going, is twice as big as it was a year ago, and a still further enlargement is in contemplation. The Bell smelter will soon be fired up under happy auspices. The mine shows nine ft of workable ore on the 400-foot level. The future is full of hope for Butte. It is already the greatest camp on earth. It will retain its pre-eminence. When its output shall be swelled by the addition of the Anaconda product, the aggregate yield will surprise the mining world and direct the attention of every man who has a dollar to spare, to the opportunities here afforded for investment. Butte, to-day, is the most independent city in the United States, and is surrounded by a mass of mineral wealth never before equalled in amount, richness, permanence or accessibility.

NEW MEXICO.

STRIKES AND SALES.—Silver City *Enterprise*, Feb.

3: Some high grade ore was recently taken from the Brush Heap mine at Kingston, owned by Elliott and Forbes; sample assays of which Mr. Elliott had made during the week give returns of 1366 oz. silver. This ore is a copper silver glance, and has but recently been uncovered. The property of the Queen City mining company, at Oak Grove, was sold under a writ of venditioni exponas on Monday last, and was bid in by I. N. Cohen, as assignee for C. P. Crawford. The mining claims and machinery brought \$6,200 and the personal property \$2,780.25. Among the machinery is a new water jacket furnace that has never been used, also two reverberatory furnaces. Alfred Jeffery returned last week, from Grafton, in the Black Range, and reports that section of the country as coming to the front in good shape. Messrs. Smith, Sansum, Cox and Jeffery are the owners of the Porter mine, an extension of the Ivanhoe, of Bob Ingersoll fame. They have a shaft 69 ft deep and considerable other development work done on the property. They have an abundance of ore which averages 85 ounces silver and \$69 in gold. A rumor has been going the rounds of the territorial press to the effect that the Bremen mine and mill would close down after the first of February. This is a mistake. The Bremen mine has produced more bullion during the past year for the number of men employed than any other two mines in the territory. The fact that the mill has been closed down for the past two weeks undergoing repairs probably gave rise to the rumors. Everything is now in shape and the mill will start to-morrow or soon thereafter. From Mr. Watson, who has had charge of the concentrating machinery at the Cooney mine in the Mogollons, we learn that a strike of some very high grade ore has been made upon the Cooney property, the extent of which is yet undetermined. Average sample assays give the returns at 1900 ounces per ton, and the streak that when struck was very narrow, had widened out within a few ft to six inches and indications of a still further widening as depth is gained. The ore taken from the other openings is of a uniformly good grade, the mill being kept running constantly up on it. Mr. Watson will arrange while here to concentrate the tailings, for which he has contracted until August next with Mr. Cooney.

LAKE LOCALS.—Lake Valley *Herald*, Feb. 9: The ore shipments from Sierra Grande are expected to exceed the past month for February. Fine ore is being taken from Nos. 10 and 25 in the Grande, as well as from other points. The total expenses of all the mines have been reduced now to \$32,000 a month, of which \$22,000 is on account of Sierra Grande. There will be a still further reduction of \$2,500 when the railroad reaches the mines, and of \$1,500 additional when the tramways are in operation for delivering ore to the train and mill. The drill is now down 112 ft in front of the office. It has passed through 15 ft of ore of a similar grade to that in the big cut. This is the upper ore body. It has not yet passed through the flint cap rock which usually overlies the higher grade ore, but has been for several days in very hard rock, making but slow progress. There is very heavy work just below town along the mountain side, and the grading of the branch road progresses but slowly. The track is laid just about half way, and is proceeding at the rate of a mile in five days. The time has been so far prolonged beyond the public expectation, that every vestige of a boom has died away. The town improves steadily, however, and considerable building is in contemplation. It is expected that the shipments from the Bella will reach as much as last month—\$60,000. The Sierra Bella company is now out of debt, with about \$40,000 in the treasury. It is now employing forty-five men as against thirty last month, and although much of the force is still employed straightening drifts, putting in tramway and getting the mine in readiness for the steam hoist, the output has already been considerable since February 1st. It would be an easy matter to take out at least \$150,000 of the rich ore now in sight by gouging for it, but Dr. Endlich proposes to mine it systematically and economically. The present workings are carefully planned, and the proposed development is fully determined. Drifts will be run like streets of a town, crossing at right angles. Of course, very much the larger portion of the ore will be left in place for the present, until it is definitely determined how far the ore body extends.

OREGON.

LITTLE DORY.—Jacksonville *Times*, Feb. 9: Miners are still idle. Wiley & Co., who are drifting in the Dry Diggings, are doing fairly. Green Bros. are still going down on their ledge near Galice creek and take out considerable fine ore. W. R. Cook is mining below his station on the road near Grant's Pass and has struck good prospects. The mines were completely frozen up for a while this week and it seems as if the clerk of the weather intended to slight the miners again this season. From Capt. Alcorn, who was over from Steamboat this week, we learn that owing to the cold weather not a great deal has been done there as yet. Shearer & Prickett have their hydraulic pipe almost ready for work.

UTAH.

PARK FLOAT.—Park *Mining Record*, Feb. 2: Several of the mining companies of the Park are talking of building a tramway from their mines during the coming summer. A general system of tramways will no doubt be the ultimate result. We are happy to state that the Sampson is opening up well, and next week we will have a full report of this mine and its late developments. Lot 21, a shipment of 14 tons, sampled 160.41 ounces silver, and 43 per cent lead, and netted the company \$2,000. The ore house is full of ore of similar quality. The company have broken the road down Empire gulch, and lots 22, 23, 24 and 25 will follow rapidly.

ORE SHIPMENTS.—Received at Mackintosh's Sampling works from the Crescent Mining Co. January 26th, 86,740 pounds; January 27th, 47,270 pounds; January 30th, 59,780 pounds; January 31st, 166,270 pounds; February 1st, 104,740 pounds. Total, 464,010 pounds. The Sampson shipped to Mackintosh's Sampling Works this week 11,120 pounds of ore. The Apex shipped 30,000 pounds of ore during the week to Mackintosh's Sampling Works. The Parley's Park mine shipped 3,000 pounds of ore this week to the Sampler.

Mining Suits.

Alexander - F. Britton, as assignee of the claim of Albert Lasey, has brought suit against Walter C. Childs, to enforce a contract made upon the sale of the Valentine mill and mine in Calaveras county, of date June 9, 1881. The complaint recites that the mine was originally patented to Lasey. Childs bought the property from Lasey, agreeing to pay \$50,000 for it, of which one-fifth cash was paid as agreed. The balance was to have been made good by the payment of three-quarters of the net profits of the mine until the \$40,000 was paid. The mine is alleged in the complaint to have been in condition to work, and it is said also that the profits would have been sufficient to pay the purchase price. Judgment is asked for the \$40,000 and interest since the date of the contract, because Childs has failed and refuses to work the mine.

The case of the United States against McMahon, in the Circuit Court, was dismissed this week owing to the complainant neglecting to produce evidence. The suit was commenced to compel McMahon, who had a homestead on certain lands at the base of Mount Diablo, to relinquish claim thereon, on the grounds that the land is mineral instead of agricultural land, as the defendant, when he applied for the patent, was aware of the mineral nature of the land.

In the case of Carney vs. the Arizona Mining company, a Sierra county appeal, the Supreme Court in bank has affirmed an opinion of one of its departments to the effect that the United States statute of May 10, 1872, requiring a certain amount of work to be performed on mining locations until a patent issues therefor, applies to placer as well as to lode or vein claim.

Meetings and Elections.

FATHER DE SNET M. Co., Feb. 7: Directors—J. B. Haggin, Joseph Clark, Thomas Brown, Thomas Bell and Thomas Menzies. Officers—J. B. Haggin, President; Joseph Clark, Vice President; Henry Deas, Secretary; Laidlaw & Co., Transfer Agents; Bank of California, Treasurer; George E. Webber, Jr., Superintendent. The following statement of the receipts and disbursements for the fiscal year 1883 was presented: Receipts, \$354,554.42; disbursements, \$258,747.13; net profit, \$95,807.29.

STATEMENT.		
January 1, 1883, balance on hand as last report	\$44,131.20	
Net earnings for fiscal year 1883	85,907.29	
December 31, 1883, disbursed six dividends, Nos. 25 to 30 inclusive		
Balance, overdraft	10,001.51	\$120,000
Total	\$120,000.00	\$120,000

REMARKS.
Total number of tons of ore milled during the year, 104,100 tons.
Average value per ton, \$3.40.

STANDARD M. Co., Feb. 7: Directors—John F. Boyd, (President); W. S. Wood and M. R. Cook, (Vice Presidents); L. Osborn, Thomas Brown, Richard H. Lumber and William Willis. At a subsequent meeting of the Directors, Colonel Boyd presented the resignation of William Irwin, who has served the company as Superintendent for seven years, and W. A. Irwin, son of the late Superintendent, was elected to fill the vacancy.

GOLDEN GATE WOOLEN MANUFACTURING CO., Feb. 11th: Trustees Messrs. William Harney, Ariel Lathrop, W. E. Brown, N. P. Smith, Adam Grant and F. P. McLennan. The trustees subsequently elected Wm. Harney, President; N. P. Smith, Vice-President; Ariel Lathrop, Treasurer; H. G. Hall, Secretary.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.
JARED C. HOAG—California.
B. W. CROWELL—Nevada.
L. M. LEHR—San Bernardino and San Diego counties.
J. J. BARNES—Sacramento county.
C. E. CURTIS—Kern and Fresno counties.
A. S. DENNIS—San Mateo county.
A. C. KNOX—Tehama, Yuba and Yolo counties.
W. M. R. McQUIDDY—Tulare county.
F. M. THIGHMAN—Fresno county.
E. H. MACK—Santa Clara county.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Lost Papers.

If any subscriber fails to receive this paper promptly, after making due inquiries at the Postoffice, he is urgently requested to notify this office by letter, that we may send the missing papers, and, if possible, guard against further irregularities.

MINING SHAREHOLDERS' DIRECTORY.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper, which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

ASSESSMENT NOTICE.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador county, near Drytown, California.

NOTICE is hereby given, that at a meeting of the Directors, held on the 30th day of January, 1884, an assessment (No. 44) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, No. 402 Front street, room 8, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the 12th day of March, 1884, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on THURSDAY, the 10th day of April, 1884, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

MARK T. ASHBY, Secretary.

OFFICE: No. 402 Front Street, Room 8, San Francisco, California.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, February 2, 1884.

At a meeting of the Board of Directors of the above named company held this day, Dividend No. 64, of twenty-five cents (25c.) per share, was declared, payable on TUESDAY, February 12, 1884, at the office in this city, or at the Farmers' Loan and Trust Company, in New York.

WILLIAM WILLIS, Secretary.

OFFICE—Room No. 29, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

The California Perforating Screen Co.
All kinds of Quartz Screens, slot or round holes; zinc, copper and brass for flour and other mills. BOOK & WAGNER, 123 and 125 Beale St., S. F.

San Francisco Pioneer Screen Works.

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the Coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Abs Co. Black also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

McCaskill's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 80x100. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

THE ROLLER ORE FEEDER.

(Patented May 28, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required. In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

AJAX and VULCAN B B POWDERS are Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

VULCAN POWDER CO.,

218 California Street, San Francisco, Cal.

GIANT POWDER,

MANUFACTURED UNDER ALFRED NOBEL'S Original and only valid Patents for NITRO-GLYCERINE Powders, which has been and still is of such immense advantage to the Miner, Railroad Man and the Engineer. All other Nitro-Glycerine Compounds are simply imitations and adulterations of the Original Giant Powder. The GIANT POWDER COMPANY manufacture three grades of Powder, which are the Safest and Strongest High Explosives in the market. The Original Nitro-Glycerine Compound, GIANT POWDER or DYNAMITE, is acknowledged by all the great chemists of the world as unapproached by any other compound. The GIANT POWDER COMPANY have acquired the exclusive right to manufacture "NOBEL'S EXPLOSIVE GELATINE," which contains 66 per cent of Nitro-Glycerine. It is still stronger than Dynamite, and even safer in handling. This explosive was used in constructing the Mont Cenis Tunnel. THE JUDSON POWDER is a black Powder owned and manufactured by the GIANT POWDER COMPANY, is from three to five times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it Breaks More Ground, Pulverizes Better, and Saves Time and Money. The only difficulty heretofore experienced by some consumers of this Powder has been that it required more time to get it to the bottom of a deep borehole. This has now been entirely overcome, and our JUDSON IMPROVED is now as dry as the ordinary Blasting Powder and runs as freely.

Triple, Quadruple and Quintuple Caps and all grades of Fuse for Sale.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ADJUSTABLE STEP-LADDER.—Edwin Markwick, Pinckney, Shasta Co., Cal. The object of this invention is to provide a ladder adapted for various heights, and which can be readily adjusted to any kind of surface, level, sloping or uneven, and at the same time may be easily transported from place to place, thereby fitting it for many uses besides those obvious ones to which a ladder is put. It consists of a two-part, or double ladder, hinged together at the base and mounted upon a single-wheeled frame, and having a back leg-brace in common, serving for either when in position; and in peculiarly adjustable extension legs with the device. The ladder is especially useful in an orchard, for the pruning of trees and for picking fruit. It can be very readily moved about. One does not have to block up the ladder to make it stand firm; and being thus firm, a man is perfectly safe on top of it. The short ladder is useful to work underneath the limbs; the main ladder on the outside of the tree. The shipping weight of this ladder is fifty pounds. The main ladder is nine feet high; short one five feet. When the short ladder is in position for use it forms and takes the place of a wheel-barrow to move the fruit from place to place. These ladders can be made to any desired size by the Union Box Factory, in this city, or by the inventor. With the general ladder one can reach to a distance of sixteen feet from the ground.

ORNAMENTATION OF FRAME MOULDINGS.—P. E. Franck, S. F., No. 292,552, dated January 29, 1884. This ornamentation of frame and other mouldings consists of a means for forming and applying the plastic material of which the ornaments are composed, so that it is formed and applied to the moulding in a continuous strip, by means of a cylindrical pattern drum or wheel. In the ordinary ornamentation a plastic material is employed, and this is usually formed in lengths by a straight pattern or mould, into which it is compressed, and afterwards is fixed or cemented on the moulding. This process is slow, and the new invention is intended to displace it, and produce a continuous strip and attach it at one operation.

HINGE.—William Patterson, S. F., No. 292,574, dated January 29, 1884. This is a device for lubricating hinges or butts of that class, having two leaves; the pintle projecting upward from the lower part of one, while the socket is formed on the upper part of the opposite leaf, known as "loose half-buts." It consists of a cup or sleeve surrounding the pintle and extending a short distance upward from the shoulder upon which the socket rests. The socket has its lower end formed with a channel or groove between itself and the plate or leaf, so that it can extend down into the cup, the edges of which thus extend up into the groove. The socket is open at the top to admit oil, and an ornamental screw-cap closes it.

RUNNING GEAR FOR VEHICLES.—Wm. A. Dan-son, No. 292,900. Dated Feb. 5, 1884. This improvement in vehicles consists in a novel construction and attachment of the pole to the forward axle and gearing, so as to relieve the draft animals from the violent shocks and blows of the pole caused by the irregular and unequal stoppage of the front wheels on the rough roads. In the ordinary construction of vehicles the pole is rigidly attached to the axle, and shares with it all shocks, which cause the pole to be moving violently from side to side. This annoys the horses and interferes with their work.

BED-LOUNGE.—August Hansen, S. F., No. 292,556, dated January 29, 1884. This improved bed-lounge has a supplemental set of legs and there are means for operating the same when the back is let down to form a bed, whereby the bed is elevated and caused to stand higher than when used as a sofa or lounge. The patent covers also certain details of construction.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers.—\$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 1/2 pages, with illustrations, well bound in cloth; 1884. Price, \$1. postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market Street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver; Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examination cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and thoroughly established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of most inventions discovered here than any other agents.

Situated so remote from the seat of Government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars of information to inventors, free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees intrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and Pacific Rural Press, 252 Market Street. Elevator, 12 Front St., S. F.

F. A. HUNTINGTON, SAW, SHINGLE, AND QUARTZ MILL MACHINERY.

We Call Attention to the Following Testimonials as to the Capacity and Durability of the Centrifugal Roller Quartz Mill:

SAN FRANCISCO, Dec. 27, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—The four-foot Centrifugal Roller Mill, bought of you in August, 1882, for the Whidden Gold Mining Company, of Shingle Springs, has given entire satisfaction, both on our own and on custom work, saving from \$5 to 90 per cent of the gold in the mill. In conclusion I will say that we are so well pleased with it that Mr. Whidden and myself are putting one of the same size on the Tohongo gold mine, near Ravenna, in Los Angeles county.

Yours truly,
P. VEASEY,
34 California St., S. F.

FINE GOLD GULCH, Nov. 10, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—In reply to your inquiry concerning the working of your Centrifugal Roller Quartz Mill, I am pleased to say that I run one of them for seven months, doing custom work on different varieties of rock, and that the mill gave satisfaction in every respect, and did all that you claim for it.

Yours truly,
BYRON JENNINGS.

GARIBALDI MINE, Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to your of the 10th inst., I take pleasure in assuring you that your Centrifugal Roller Quartz Mill gives entire satisfaction, and I can heartily recommend it to mining men who want a cheap and efficient crusher.

Yours truly,
E. I. PARSONS, Supt.

32 WASHINGTON AVENUE,
SAN FRANCISCO, Dec. 29, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—Having run one of your Centrifugal Roller Quartz Mills on sample lots of rock from more than twenty different mines, I must say that in every instance it has given the best of satisfaction in every particular; and I recognize its superiority over any other mill manufactured.

Very truly yours,
D. O. MOWRY.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

CAPACITY AND DURABILITY GUARANTEED.

F. A. HUNTINGTON, 45 Fremont St., San Francisco.

SAMPLE LOTS OF ORE WORKED.

WHERE A MACHINE CAN BE SEEN IN OPERATION.

CENTRIFUGAL ROLLER QUARTZ MILL.

The work done by the Centrifugal Roller Quartz Mill, during the past two years, on various mines and different kinds of rock, PROVES ALL THAT IS CLAIMED FOR IT, VIZ:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

SONORA, CAL., Dec. 1, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to yours of recent date, inquiring about the Centrifugal Mill which I bought of you, I will say that I have run the mill four months on hard rock; and I take pleasure in adding that the mill has in every way given the best of satisfaction.

Yours truly,
J. H. NEALE.

GARIBALDI MINE,
Calaveras Co., Cal., Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In answer to your inquiry concerning the working of the five feet Centrifugal Mill, bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

Very truly yours,
O. B. SMITH.

F. A. Huntington Esq., San Francisco, Cal.—
DEAR SIR—Your Centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Co. property at Shingle Springs, El Dorado Co., Cal., about four months, and it has done good and satisfactory work, a greater proportion of gold remaining in the mill than in the stamp battery.

FRED JONES, Supt.

HILDRETH RANCH, Fresno Co., Cal.,
January 11, 1884.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In regard to your mill (Centrifugal Roller), I have crushed about 500 tons of rock in the mill, and am glad to say that it has given entire satisfaction, and can recommend it to the public as the most expeditious and least expensive method for crushing and milling ore that I have ever seen.

Truly yours,
THOS. HILDRETH.

HEINE PATENT SAFETY BOILER. RISDON IRON AND LOCOMOTIVE WORKS,

Sole Agents for the Pacific Coast.

Corner Beale and Howard Sts., San Francisco.

Economy in space and fuel.
Safety at high pressures.
Freedom from scaling.
Equally adapted for power and heating purposes.
Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity.
Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

HARTFORD STEAM BOILER INSPECTION & ISS. CO.,
ST. LOUIS, Mo., June 21, 1883.

Messrs. Adolphus Meyer & Co., St. Louis, Mo., GENTLEMEN: You ask my opinion as to the practicability of using the "HEINE PATENT BOILER" on a Ferryboat crossing the Mississippi at this point. In reply I beg to say that I have been an engineer along the Mississippi valley for nearly forty years, and now hold a P. S. Inspector's certificate as First Engineer. I have no hesitancy in saying that the "HEINE" boiler is as safe as any type of boiler used on the western rivers. It has no flues with an external pressure that would be liable to collapse, and the drum is a plain cylinder, all well stayed. It is easily cleaned, and can be inspected in any part.

Very truly,
JOHN S. WILSON, Inspector.

It is both serviceable and safe, and I would not hesitate to use it on my River Steamboat.

Very respectfully,
W. W. COREY,
Chief Engineer St. Louis & M. V. T. Co.

OFFICE OF ST. LOUIS & MISS. VALLEY TRANS. CO.,
ST. LOUIS, Mo., July 6, 1883.

Messrs. Adolphus Meyer & Co., GENTLEMEN: I have thoroughly examined the "HEINE SAFETY BOILER," and have been very favorably impressed with it. In my opinion

Referring to the above endorsement by Mr. Corey, we cheerfully endorse him as a competent and careful Engineer, being Chief Engineer of our line.

HENRY C. HAARSTICK, Pres't.

Cornish Roll Grinder.

We give herewith two illustrations—front and back views—of a new machine, built by "The Tanite Company," of Stroudsburg, Monroe county, Pa., the object of which is to grind Cornish rolls in place. The machine here represented carries a Tanite emery wheel of 18 inches diameter, and one and a half inches in thickness on a one and a half inch steel arbor. The machine shown weighs 780 pounds. The frame K is designed to be bolted on top of the frame of the Cornish rolls. By means of the wheel and rod G a lateral movement is communicated to the emery wheel, which, in this size of a machine, will travel over a Cornish roll 18 inches long. The wheel F gives a vertical motion of 6½ inches, thus allowing the emery wheel to be worn down to its flanges. The pulley B is 4½ inches in diameter, and the pulley C is 3 inches in diameter.

The success with which Tanite emery wheels have been used in grinding steel, chilled iron, phosphor bronze, etc., would lead one to believe that they could be used successfully on any metal, however peculiar, of which Cornish rolls are made. This belief is substantiated by a letter from F. Koerner, Superintendent of the Canada Consolidated Gold Mining Company, Deloro, Ontario, to the makers of the machine. He says: "The emery grinder for trueing up our Cornish rolls in place, which you built for us some time since, is a fine success. The expense of removing the rolls out of the housing, turning them off in a lathe, and replacing them again, would be double the cost of the machine, not to speak of the loss of business caused by the ten times greater delay of such removal."

If the above strong statements should prove true in general practice, then this machine ought to be promptly and widely introduced in all our mining regions. Messrs. H. P. Gregory & Co., of 2 and 4 California street, San Francisco, and the Hendrie & Bolthoff Manufacturing Co., of Denver, are the Western agents for this machine. In quartz mills where the rolls are used, a machine of this kind would save considerable time and expense.

A Deep Air Gallery.

The opening of the connection between the north and south drifts on the 3100 level of the Union Consolidation mine on the Comstock, completes a fine large air gallery running through the leading north-end mines at the great depth of 3,100 feet. From it supplies of air may be led to all points on the levels above where work is going on. The air current in this deep gallery moves more rapidly than it does in any of the upper galleries. The deeper the point at which such connections are made the more rapid the air circulation. As to the volume of air in this deep gallery the Virginia Enterprise furnishes some interesting facts: The current of air rushes through the gallery at the rate of 650 feet per minute, or seven and a half miles an hour. The volume of fresh surface air thus introduced upon the 3100 level amounts to 20,000 cubic feet per minute. When we consider that 500 cubic feet of air is sufficient for one man for twenty-four hours—that every minute enough air passes into the mine to last forty men twenty-four hours—we begin to see the great value of this natural circulation of air as compared with that which can be forced down into mines by means of blowers. Each candle in a mine consumes about the

same amount of air as is required for a man, but with a supply of 20,000 cubic feet at command at the lowest point in the north-end mines, it will be seen that many men may be worked and much prospecting economically done. Such a great volume of air will soon sweep out all the foul gases and heated air that

Academy of Sciences.

Mining Claims in Canyons.

In the last number of the MINING AND SCIENTIFIC PRESS was given a decision of the Secretary of the Interior to the effect that where part of a legal subdivision is non-mineral land a location that follows the mineral deposit conforms to the public surveys as nearly as practicable. This is an important point, for the reason that the law requires "that placer locations upon the surveyed lands shall conform to the public surveys in all cases, except where this is rendered impossible by the previous appropriation or reservation of a portion of the legal subdivision of ten acres upon which the claim is situated." Because of this provision of the law the Commissioner of the Land Office decided that a miner who laid out a claim in a canyon in this State, following the bed of the stream between the precipitous, non-mineral and uncultivable banks, did not conform to the surveys, and would not get a patent.

The Secretary of the Interior, however, very properly objects to so narrow a construction of the law. While the sections of the law provide for ten-acre subdivisive surveys, they also contemplate cases where it is not practicable to conform the location to such subdivisive lines. They do not limit such cases to those where there has been a prior appropriation of a part of the subdivision, but extend it to every case where it may be impracticable to so locate the claim. The expression "as near as practicable" is therefore to be read "as near as reasonably practicable." In the placer-mining statutes Congress has evidently intended to provide for cases where the situation of the deposits is such that conformity of the location with subdivisive lines is unreasonable. It was the intention of the mining laws generally, to permit persons to take a certain quantity of land fit for mining, and not to compel them to take such a quantity irrespective of its fitness for mining. The act of July 9, 1870, which expressly required placer locations to conform to the lines of the public surveys, was unreasonable, a hardship, and in contravention of the established custom of the mining regions; therefore it was modified by the act of May 10, 1872, so as to provide for the exceptional cases. Such an exceptional case is that where the entire placer deposit in a canyon within certain limits is claimed, and where the adjoining land on either side is totally unfit for mining or agriculture.

THE ATOMIC WEIGHT OF ANTIMONY, by T. Bongaril. The author, at the commencement of his paper, reviews the various methods proposed for the determination of the atomic weight of antimony, their incidental errors and their results. The process adopted by him consists in the oxydation of the sulphide by ammoniacal hydrogen peroxide, as suggested by Claper, and the precipitation in the form of barium sulphate. Metallic antimony was first prepared by electrolysis of a solution of the sulphide in excess of ammonium sulphide, and purified by fusion with sodium carbonate. The regulus was washed with dilute hydrochloric acid, cleansed with sand and dried. The metal was dissolved in potassium sulphide and the solution precipitated with sulphuric acid. The precipitated sulphide was then oxydized by hydrogen peroxide in an apparatus in the form proposed by Claper and the solution precipitated by barium chloride. The results of twelve determinations: Ba=136.8, S=31.98, O=15.96 gave a mean of 120.193.

A LARGE wheel, connected with the hoisting works at the Idaho mine, Nevada county, broke on Friday night, which will put a stop to the use of water in that connection for several weeks. The hoisting works will be run by steam until a new wheel is procured from San Francisco.

late Dr. Englemann, the eminent botanist. This will be published in next week's PRESS.

Mr. Charles Wolcott Brooks read from the last number of *Nature* a description of the phenomena attending the volcanic eruption of Krakatia.

THE gross earnings of the Union Pacific Railroad for the last year were \$29,761,100; expenses, \$16,670,000.

CORRESPONDENCE.

Disturbances of the American Continent.

Recent Volcanic Activity.

EDITORS PRESS:—That the whole American continent (at a period many thousands of years subsequent to man's first appearance on earth) has been again subject to a scene of violent volcanic activity cannot be ignored. This fact is abundantly evidenced by not only legendary lore, but what cannot be disputed material facts as collateral evidence of the pre-existence of a populous race of people considerably advanced in the arts and sciences, of which we have no written history. And unless the legend which I will hereafter relate can be taken as proof of their origin and history, we have nothing left to tell the tale but their ruined towns, fortified cities, mounds, pyramids, works of art and animal remains that are scattered over the whole American continent, silent monuments of their previous existence.

In the Lake Superior copper mines detached masses of metallic copper are found, too marked, and by their side the very tools that the ancient miner used and left in his hasty flight on receiving the dread warning of impending calamity.

In the Western States we find the evidences of their existence in abundance, and in Mexico, New Mexico and Arizona, towns and ruined cities, covering large areas with every evidence of a civilized people, of which the present inhabitants have no record.

In South America there is abundant proof of their former existence. The writer had occasion to cross the Desert of "Atacama," and en route he discovered the ruins of a large town, of which his guide could only tell him that "the oldest inhabitants" were ignorant of its history or the race that inhabited it. It had been a walled city of mammoth proportions; the crumbling walls and ruined houses of sunburned bricks, the labyrinth of streets, broken and unbroken, utensils of glazed pottery of classic forms and design, denoted a high state of civilization. One specimen that the writer selected and preserved as a memento was a water jar that would hold about a quart. It was of Grecian form, the neck long and slender; the mouth-piece for the water discharge was so curiously and ingeniously constructed that the escape of the water would occasion a noise like the chirping of a bird. That its inhabitants perished by a sudden and violent death with but little warning is proved beyond peradventure. An immense field of many acres in extent adjacent to the ruined city was covered with their remains, whitened skeletons of men, women and children lying in groups, pairs and singly—here a male and female lying side by side, there a mother and her child; some of the skeletons were of giant proportions. This was no burial ground was proven by places devoted to that purpose within the city limits. Should it be proven that this terrible holocaust of destruction swept over the whole continent at a time contemporaneous with the scene described it would account for much hitherto unexplained phenomena. There can be but little doubt but that the cause of this wholesale slaughter was owing to poisonous and mephitic vapors and gases that escaped or were evolved from the earth's crust during some violent volcanic disturbance. The inhabitants left the city and sought the plains from fear of falling houses that were thrown down from the effects of an earthquake. A wholesale slaughter ensued, not one being left to tell the tale or bury the dead.

Legendary Lore Relating to Volcanic Disturbances.

In Arizona, on the mesas near the Colorado canyon, there is a tribe of Pueblo Indians known as the "White Indian," many of them having light hair and blue eyes. They are probably of European origin, are house dwellers, live in communities and are governed by a chief elect, whose word is law. They are industrious, peaceable, follow agricultural and pastoral pursuits, and make and wear woolen goods. In the manufacture of the *Poncho* or *Serape*, which is worn by the Indian and Mexican, they excel, and exchange these products for such articles as they require, and do not produce. A horn is blown at 6 A. M. as a signal to commence their daily labors, and again at night to cease. Their houses are raised from the ground, with doors on the roofs and ladders used in place of stairs or steps to enter. They have no written language, but their historical legends are handed down from father to son. The history of their origin is the first thing they learn their children, as soon as they are old enough to understand and commit to memory. They are very jealous of not making known to strangers, or even to other tribes. They guard it as a tribal secret, with penalties for divulging. A well known frontiersman, Capt. John Moss (now deceased) stood in high favor, not only with this tribe, but with all of the Indian tribes of Western North America. He spoke 14 different Indian dialects, understood their signals of war and peace, and was trusted by them as a trustworthy friend. His Indian name was universally known as "Narrowgumpe" (never die). He learned their legendary secret and imparted it to the writer. It was in brief as follows:

Their forefathers, with their wives and fami-

lies, came to Arizona from over the "Big Waters" (the ocean.) They found a fertile country, covered with vegetation; deciduous trees, fruit trees, berries, wild grasses, wild game and birds in abundance. The country was well watered and stocked with a great variety of fish. They soon multiplied and increased; they lived in communities, built towns and houses, cultivated the soil, became numerous and were happy and contented.

A terrible calamity overtook them; the sun took fire and burnt up; the heat was unendurable; trees and vegetation were consumed; the ground rocked too and fro like a troubled sea; the rivers dried up; darkness spread over the land, which continued for many moons. They crawled into caves and dug holes in the ground for shelter, but most of them perished. When a new sun was born it was again light, but their hitherto beautiful country was a barren waste; their towns destroyed, and houses in ruins. The remaining few survivors assembled together and with their wives and children migrated to the low lands bordering the "big rivers" (the Colorado and Gila) and commenced life anew. They increased again and became a numerous and prosperous people; but the condition of the country had changed, there were no longer beautiful running streams of clear water in the interior. Their main supply was from the big rivers, the Colorado and Yuma, from which they brought water for irrigating purposes through canals and aqueducts to their farms.

[An extensive system of canals and aqueducts is still to be seen in Arizona and California, on the Colorado bottom, and in San Bernardino county, but the history of the builders is unknown.]

One day, without warning, a tribe of ferocious Indians from the north swept down upon them, and as they were unaccustomed to war-like pursuits, soon conquered, despoiled and enslaved them. A portion escaped and fled to the mountain ranges, and dug habitations in almost inaccessible places in the stony cliffs that border the "Big River" (Colorado), the walls of which were nearly perpendicular; but they ascended and descended to their cliff dwellings by steps cut in the solid rock, and subsisted on fish from the river. In time they emerged from their hiding places and settled on the mesas or tablelands bordering the river banks (where they now live.) They soon collected a few sheep and goats, and followed agricultural and pastoral pursuits. They are not numerous, but industrious and happy at the present time.

They, like other Indian tribes, believe in a Supreme Being, evil spirits and good spirits. They believe in future rewards and punishments; their heaven is the happy hunting ground, where they reunite with their deceased friends and relatives.

After death, upon reaching the spirit land, they are met by all their deceased relatives who have gone before them, and presented with an ear of corn. Should they eat it when offered they are remanded back to whence they came to pass another term of probation in this world. Should, however, they store it in their pouch, their friends prepare for them a big "eat" (feast) of all the Indian delicacies known, and their troubles are over for all time, while the bad Indian goes to the Indian "Hades," where he can see the good Indian enjoying himself with his friends in which he is not permitted to participate.

X MAX.

White Oaks, New Mexico.

Californians and California Machinery Needed.

EDITORS PRESS:—Mining matters in New Mexico just now attract but little attention, nor do they have quite justice at the hands of a part of the mining press. The advent of the American in force, and the inauguration of American methods and system in prospecting, mining and reduction (except in Grant county), dates from 1879. The production of values by the mines of New Mexico hardly equaled a million in 1880, and did not pass a million and a half in 1881, and these amounts were chiefly from Grant county. Progress has since been really rapid. For instance, prior to the end of 1881 the actual product of Socorro county had been nominal. In 1882 she produced gold \$200, silver, \$140,000, base bullion, 1,039 tons, valued at \$113,812, and shipped 1,000 tons of ore, valued at \$186,800. The shipments from a single smelting plant in the last four months of 1883 exceeded half a million. The production of the county for 1884 will probably reach the total of \$2,500,000, perhaps \$3,000,000. The product of Grant county for 1883 passed \$1,500,000. For the Territory at large a product of, say one and a half millions in 1881, became \$3,667,000 in 1882, and \$6,500,000 in 1883. In all these estimates of course copper and lead are included.

The gold camps of Lincoln county have been especially unfortunate. They are at a distance of 100 miles from the railway; capital has been naturally attracted to regions easier of access. They have had an overproportion of men from Eastern and Southern agricultural States wholly ignorant of mining. What capital has been brought into them has come from and with Eastern men innocent of any mining experience. Such machinery as we have has been "experimental" largely. At this point (the most central in them) are three mills, the first erected in June, 1881, a ten-stamp Hendrie & Botthoff, of good construction. It was erected in the bottom of a gulch upon a foundation of "wash,"

without battery, blocks or piles, and with insufficient power. Short copper plates and raw quick have been the only agencies employed to save gold; none of the owners had any previous experience. It stumbled along, making continuous failures, for a long period. It is now worked as a custom mill by one of the owners, who, by dint of hard knocks, has acquired some knowledge of the work. It now accomplishes as much work as a mill so constructed can, and saves from 50 to 60 per cent of assay.

In the spring of 1882, the Homestake Co. erected a \$45,000 mill to work Homestake ores by the "electric process" of Professor Remsen. That the process and the machinery by which it was applied was entirely "original" was undoubted. The total results were about 3 ozs. of gold, 1,500 lbs. or so of dirty quick and a lot of old iron. In the spring of 1883 the Wilmington, (Delaware) firm of Benson, Thomas & Chandler put in a mill, the pulverizing part of which was two "Tasker" machines; for gypsum and other comparatively soft material they will doubtless serve. They failed, as might be supposed, upon the White Oaks ores, which are uniformly both very hard, and very tough. Two good stamp mills are promised this year; one of them at least will be built by an experienced California firm and the other by a man of wide experience in Colorado. Nothing but proper machinery under skilled direction is needed to make the gold camps of Lincoln county wealthy and prosperous. There are here the finest gold ores, east of the Continental divide, and in rich abundance; they are of unusually good grade. The ores of this district will, under skilled and proper treatment, yield an average clean-up of from \$38 to \$40 per ton.

Fifteen miles south of us, in Nogal canyon, is a fine 15-stamp mill of good construction, and under intelligent management. It is doing well. A concentration mill will be put in on the Bonito canyon, still 8 miles south of Nogal, in the spring. A fine 2-stack smelting plant has just been finished at Organ City, 18 miles northeast of Las Cruces. The Organ mountains can give it an abundance of ore, and its success is probable.

The Torrence mine and mill at Socorro, now for some time idle, have been sold to the Cabinet Mining Co. The new owners will resume the extraction of ore from the Torrence mine, and haul ore from the "Cabinet." A fine 70-ton smelting plant upon the A. T. and S. F. railway at Socorro has lain idle most of the time since its erection in 1881-82. It is understood to have been sold to parties who will make it actively useful. A majority of the works and mills now active are intending to increase their facilities during the year. Enormous amounts of ore and concentrates are passing them by rail, bound for Pueblo, Denver and Argo. The whole mining field is bright, with signs of progress and vigor.

It is unfortunate that we have so few Californians among us. There is no field more favorable for the investment of their capital. New Mexico has passed the era of "prospecting millionaires," and property can now be bought anywhere in the territory for what it is worth in the eyes of a conservative business man; we need their experience and system; we also need their machinery and methods. When one of your great building firms sent an agent here two years ago, the field was not ripe. The connections of nearly all mine owners of that day were Eastern, and they of course went East for their plants. They have learned something, and your men can do business with us now.

Good miners also need have no fear of coming to New Mexico. The climate is superb. The country will suit them, and they are needed. Good miners, in the sense that the term is used by an old mining engineer, are scarce. I doubt if some of our Eastern superintendents have ever seen one. Mere drill pounders are plentiful, of course.

D. J. M. A. JEWETT.

White Oaks, Feb. 9.

ORE PRICES.—The Benson Mining and Smelting Company pay the following rates for ore: Lead ores containing from 35 to 45 per cent lead, 30 cents per unit for the lead and \$1 per ounce for the silver, less \$15 per ton working charges; lead ores containing 45 to 60 per cent lead, same price for lead and silver, less \$10 per ton working charges; lead ores going above 60 per cent lead, same price for lead and silver, less \$5 per ton working charges. Ordinary rates for dry ores.—*Mohave Co. (Arizona) Miner.*

SAVING FINE GOLD.—The *Amador Sentinel* understands that Mr. V. Yelmini, at the Oneida mine, has discovered a process by which the fine float gold may be saved in placer and gravel mines. By his process, it is said that mines which heretofore would only pay about 25 cents to the hand will now pay from \$4 to \$5. He intends to patent his invention, and then we may expect a revival in placer mining in this vicinity. Under this process Mr. Yelmini is successfully operating his mine in Oneida valley.

OLD MEADOW LAKE.—The snow is ten feet deep at Lake Fordyce, which place is about the same altitude as Cisco. At the ruins of the old town of Meadow Lake it is supposed to be from twelve to fourteen feet, although no outsiders have been over there yet to measure it. The few who stop at the old town, with the foxes and the coyotes, have it all to themselves.—*Virginia Enterprise.*

Colorado Mining Outlook.

A correspondent of the *Colorado Miner* says: The mining industry of this great State has made highly encouraging and substantial progress during the past year. The silver lining of the future is tinted with brilliant prospects of solid, enduring wealth. Throughout the whole extent of the mining regions men have been eminently successful in bringing to light new and valuable claims of gold and silver. The fabulous richness of some of the new discoveries is a sure guarantee that the future of our great industry here will be one of unbounded prosperity. An experience of many years in mining, and the examination of mines in Boulder, Gilpin, Clear Creek, Summit and Lake counties, has convinced us that the mineral wealth of the Rockies is practically inexhaustible for ages upon ages to come.

In this county, the old stand-by of the State, satisfactory and highly encouraging results have crowned our every effort with abundant success. Our mines in all portions of the county are yielding large quantities of good pay ore. It seems as though the great treasure box of the world had been hidden away in these grand old mountains for the express purpose of teaching earth-bound mortals not to be astonished at acquiring fabulous wealth by honest industry and toil in a few days. Stand by two old prospectors as we have done, and see them dig out of mother earth the glittering "stuff," worth, laid on the dump, \$50 per pound. Only a pocket, some say. Yes, but the pocket holds out, and the old delvers are now wealthy, and the mine improves in the quantity and quality of ore as the work of development goes systematically on. This is not an isolated case. Many who went to Leadville during the excitement of '79 with empty pockets are now in the enjoyment of nice little fortunes. What this county, as well as many others in the State, needs is proper and systematic development. Yes, we greet the beginning of 1884 with joyous feelings. The gloom and doubt in regard to the character and extent of the mineral resources of this county have passed away, and a universal feeling of confidence is felt by every one that a state of permanent growing prosperity has been reached. This well-conditioned state of affairs has been accomplished by labor, the imperial power of all communities. The toilers in the mines have done noble work. With heavy, sledge-hammer blows they have proved, by actual development, that wealth— inexhaustible wealth—can be mined out of our silver-veined mountains. Contrast the present state of affairs here with the past, when croakers and scientific gentlemen (?) pronounced the mines of Clear Creek county a failure. Verily a bright and glorious future is in store for the mines of the Centennial State.

Mining Ditches and Irrigation.

In the course of an article on the effects of the debris decision, the *Nevada Transcript* says:

The report about the abandonment of the ditches was correct, for it referred only to the systems feeding that part of the county situated above Nevada City, and including the ditches of the Eureka Lake and Yuba Canal, North Bloomfield, Omega and Milton Companies, and having a total length of 500 miles.

As to the South Yuba Canal Company, it has, since Judge Sawyer's decision, practically abandoned the Dutch Flat and Blue Tent ditches, about 35 miles in length, and is now keeping up the remaining hundred miles in order to supply the town water works of this city and Grass Valley, and furnish motive power to such quartz mines in Nevada and Grass Valley townships as are fortunate enough to be within reach of it. Although in operation for thirty years, the sales of the company for irrigating purposes have never exceeded \$1,000 gross per year, and seldom have they reached that figure.

The original construction account of the company amounted to \$1,000,000 for the 135 miles of ditches and the seven artificial lakes it has built on patented ground belonging to itself. It probably has the most extensive and complete water system in America. The record shows that from 60 to 70 per cent of the water it sells has to be stored in its reservoirs for six months before the patrons want it. It has until now given employment to an average force of about 75 men and a living to their families. The current expenses of the property last year were, for instance, \$57,000.

And now we come to an important and unpleasant fact that cannot be ignored and need not be disguised. The revenue derived from the sale of water for power, domestic and irrigating purposes in Nevada and Grass Valley townships, under the most favorable conditions, cannot be made to equal the bare expense of bringing that water by itself to the market, and the company has good reasons to seriously ask, as it is doing, if the abandonment of the whole system is not the only resort left to it.

The Excelsior Company, with its large agricultural possessions, enjoys certain advantages that none of the other ditch owners do, and may manage by great care to weather the storm in case the Sawyer decision stands; but men who have grown gray in the business say there are not very brilliant prospects even for that company.

MECHANICAL PROGRESS.

Improvement in the Bessemer Process.

A patent has recently been issued to Captain William R. Jones, manager of the Edgar Thomson Steelworks, for an improvement in the method of treating the metal in a Bessemer converter when the temperature of the bath becomes too high. The methods hitherto employed for obviating this difficulty have been to add scrap metal until the heat was sufficiently reduced. The improvement suggested by Mr. Jones consists in the introduction of steam into the molten metal in conjunction with the air blast. In the use of this method Mr. Jones found that the length of time during which steam should be admitted to the converter depended upon the size of the pipe delivering the steam, as well as upon other conditions, such as the nature of the metal, the pressure and volume of the air blast, etc. He also discovered that in working a 10 ton converter with steam delivered at about 50 lb. pressure through a pipe 1½ inch in diameter, the steam may be forced with the air about six minutes, or from one-third to one-half the length of the blow. It was found advantageous in some cases to inject the steam with the air blast for a short time just before the completion of the blow, if the heat of the metal was shown by the flame to be excessive, and, in fact, the steam might be introduced at any time when the appearance of smoky vapors or other indications in the flame familiar to the operator show that the metal is becoming too hot. Instead of using the steam at the commencement of the blow, it may be introduced at some later stage, or be used continuously throughout the entire period of conversion in connection with the air blast. The inventor adds that it may be expedient to introduce, instead of steam, a spray of water in a finely divided (atomized) condition, together with the air blast, though, as the chilling effect is much greater than where the steam is employed, the more equitable action of the latter makes its use preferable in practice. Mr. Jones claims as a marked advantage of the present invention that it allows for the use of a grade of pig metal which shall be high enough in silicon to avoid the presence of an objectionable percentage of sulphur, and yet, despite its greater heating capacity, be under the easy control of the operator, who is able to counteract any harmful increase in temperature that may develop during the blow. He makes mention in his specification of the previous use of steam in connection with converter charges, but claims that it was never employed in this peculiar way, or for this same purpose.—*Iron Age*.

Unsolved Problems.

There are two problems, the attempts to solve which have so far baffled the efforts of mechanical skill. These are perpetual motion and navigation of the air. It is only dreamers who now give any thoughts to perpetual motion; not so the navigation of the air. Earnest minds are still engaged in the attempt to prove that the theory can be reduced to practice. Years of patient study and the expenditure of enormous sums of money have failed to convince the present generation that it will witness a triumph in either of the devices named. The public is half disposed to believe that aerial navigation is attainable. That the principle exists is demonstrated by the flight of birds; but the question arises, who is to give it successful application to machinery? A number of persevering toilers on the project have, at different times, summoned spectators to see and be convinced that they had made the grand discovery. Their machines would never, however, ascend. The attraction of gravitation was too much for them, and instead of cleaving the air majestically, they have made an inglorious descent to the earth. There was some hitch detected—some obstacle to be overcome—and thus it has been since inventive genius first asserted its ability to master the interposing complications. But, we are informed, an Englishman named Lenfield has got it at last! He has constructed a flyer, with which he expects to go through the air, in any direction he pleases, at the rate of sixty miles an hour. When he has accomplished this, he will cross the ocean to pay us a visit in his remarkable machine. There is no need of fretting, or any anxiety about his coming. A comet is just now visible in the heavens. After taking its departure, it will not return until the expiration of seventy-one years. Those of our young people who may be fortunate to survive so long are advised not to be astonished, if, when it makes its reappearance, perpetual motion and air navigation still remain things of the imagination only.

Steam Boilers.

A steam boiler, to produce economical results, should be constructed and set so as to permit a free combustion of the fuel and give a sufficient volume of space for the hot gases to combine, in a manner calculated to effect the utmost production of heat due to the fuel consumed. Combustion of fuel is the chemical combination of the substance of the fuel with the oxygen of the air. A mechanical mixture is a composition in which the ingredients retain their natural properties; steam is a mechanical mixture of

heat and water; atmospheric air is an invisible gas, produced by the mechanical mixture of two other gases, viz., oxygen and nitrogen. A chemical combination is an action in which certain elements and substances are absorbed and destroyed in the production of some other element or substance. Heat is a product of the chemical combination of the element oxygen with a combustible substance; and to produce the maximum volume of heat from a given weight of fuel, it is necessary that a proper quantity of oxygen, under correct conditions, be admitted to the furnace and combustion chamber. The maximum rate of heat having been provided for, the surface of the boiler exposed for its operation should be of sufficient extent to allow the necessary time for transmission of heat to the contained water. When the heating surface is insufficient, the heat is certain to be carried through the flues or tubes and into the up-take before it (heat) can be absorbed to an economical extent. There must be, also, ample room for the escape of steam to the surface of the water; and after it has passed above the water it would seem as though it was necessary to bring it (steam) again in contact with some heating surface to thoroughly complete the evaporation and even superheat the steam slightly before it is finally allowed to pass to the engine.—*American Locomotive Engines*.

AMERICAN STAMP MILLS THE BEST.—The *Ironmonger* is slightly disconcerted at the fact that contracts have been made by some of the promoters of Transvaal gold properties with American firms for the machinery to be used in treating their gold ore. It pathetically asks how it is that the necessary machinery cannot be procured in England or Scotland, and recommends to the British engineering firms to lose no time in adapting themselves to the wants of the day. That our mills are vastly superior to anything English mining machinery firms can turn out, is, we believe, beyond all question. We need only point to the success of American stamp mills in Venezuela, Colombia, Honduras, and in other States in Central and South America. English engineers would, however, find that it takes more than mere copying to attain their excellence. Every detail is the result of long experience, and our friends across the Atlantic would rapidly go through the usual fate of imitators, that of failure.—*Engineering and Mining Journal*.

SCRAP FORGINGS.—Scrap forging are not necessarily good or bad; it depends wholly upon the scrap. Blacksmiths are fully aware of this and take pains to select it carefully. What the practice in England may be we know not, but in this country scrap is carefully culled, not by boys, however. Forgings are not made from a pile of old waste-iron, currys, combs, pokers and rubbish generally, but from boiler-plate (cuttings and punching included) which does not vary greatly in quality, and is generally the very best. Horse-shoes are also utilized, and concerning these last there is no question at all as regards quality. Forgings may be made now, as they have been in days past, from the scrap-heap direct, but they are quite apt to be unworkable in machine tools. There is sure to be a hard streak in the journals of a shaft which no tools will touch, and the surfaces where planed are of as many shades as there are kinds of iron.—*Mechanical Engineer*.

A REMARKABLE STEAM ENGINE.—An English firm have recently completed a small, light compound engine, which, in point of weight, eclipses anything heretofore built. This engine is made of steel and phosphor bronze; all parts are built as light as possible, the rods and shafting and all parts possible being bored out to reduce weight. At a speed of only 300 revolutions a minute they indicate over twenty horse-power, and weigh but 105 pounds all told. This engine would give fully thirty horse-power actual at a piston speed of 500 feet a minute. The size is three and three-quarters high pressure, seven and a half low pressure and five stroke. That thirty horse-power can be had from a proper utilization of steam and proper distribution of 105 pounds of metal is certainly most astonishing, especially so considering that the engine is compound.

THE DIAMOND DRILL AS AN EXPLORER.—We have lately, says the *Scientific American*, seen samples of cores cut by the diamond drill that are marvellously curious. Sections of rock and ore drawn up from hundreds of feet below the surface showing the stratification and its inclination, with all the varieties of its composition; the veins of ore and its boundaries and dip are well marked and better measured than if the miner was down in the depths of earth sending up his samples; and what is more valuable, the diamond drill sends up the samples partly polished—so smooth is its cut that you have but to wet the core to bring out all the variegated hues of rock and ore. It matters not as to size—one inch or two feet is within the grasp of the modern explorer.

GAS ENGINES are now made of from ½ to 70 horse-power. Medium sized gas engines, say 16 horse-power, will run on a consumption of fuel of 1.2 pound of coal per horse-power per hour, which is about half the fuel required for the most economical steam engines of the largest size.

SCIENTIFIC PROGRESS.

The Atomic Theory.

The following extract from Wurtze's on "The Atomic Theory" gives a very clear and succinct account of the vortex theory of atoms, which is now being much discussed by scientists:

"In these latest times a theory has arisen which seems to give a mathematical demonstration of the indivisibility, or rather of the peculiar and eternal individuality of atoms. I refer to the vortex atoms of Sir William Thompson.

"Chemists can form an idea of this vortex motion by recalling to mind the rings which rise in still air whenever a bubble of phosphorated hydrogen bursts upon the surface of the water, and the rings which certain smokers are able to make are familiar to all. An apparatus has been constructed by which they may be produced at will. It is a wooden box, one side of which is furnished with a circular opening and the other formed of a tightly-stretched cloth. In the interior of the box fumes of sal ammoniac are produced, which are driven out by a sharp blow on the elastic side. A ring of smoke is then seen to issue from the opening and to move freely through the room. In this ring all is motion; and, independently of the motion of translation, the smoke particles roll over each other and execute a rotary motion in every section of the ring. These motions take place from the interior toward the exterior of the ring, in the direction of the motion of translation, so that the entire mass of air, or smoke which forms the ring, revolves continually round a circular axis, which forms, as it were, the nucleus of the ring. There is this remarkable fact in this rotary motion, that all the particles which are situated upon one of the curves which can be drawn in each section of the ring are indissolubly tied down to their circular paths, and can never quit them; so that the whole mass of the vortex ring will be always formed of the same particles. This theorem was proved by Helmholtz, in 1858. This eminent physicist has analyzed the vortex motions which would exist in a perfect fluid free from all friction. He has proved that in such a medium vortex rings, bounded by a system of vortex lines, are formed of an invariable quantity of the same liquid molecules, so that the rings can move, and even change their form, without the connection of their constituent parts ever being broken. They will continue to revolve, and nothing will be able to separate them, divide them or destroy them. Those existing in the liquid will exist there forever, and new ones can only be excited in it by a creative act.

"The smoke-rings of which we have spoken above would give a perfect representation of these liquid vortex rings if they were formed and moved in a perfect fluid. They are not so; but such as can be formed can serve for the demonstration of some properties of matter in vortex motion. They are endowed with elasticity and can change their form. The circle is their position of equilibrium; and when their form is altered they oscillate round this position and finally re-assume the circular form. But, if we try to cut them, they recede before the knife, or bend round it without allowing themselves to be injured. They gave, therefore, a material representation of something which would be invisible. And when the two rings meet each other they behave like two solid elastic bodies. After the impact, they vibrate energetically. It is a singular fact that when two rings are moving in the same direction, so that their centres are situated upon the same line and their planes perpendicular to this line, the hinder ring contracts continually, whilst its velocity increases; the ring in advance, on the contrary, expands, and its velocity decreases, until the other has passed it, when the same action re-commences, so that the rings alternately pass through each other, but, through all these changes of form and velocity, each preserves its own individuality, and these two circular masses of smoke move through the air as if they were something perfectly distinct and independent. These curious experiments were made in England.

"Helmholtz, therefore, has discovered the fundamental properties of matter in vortex motion, and Sir William Thompson has stated: This perfect medium—these vortex rings, which move through it, represent the universe. A fluid fills all space, and what we call matter are portions of this fluid which are animated with vortex motion. There are innumerable legions of very small fractions or portions; but each of these portions is perfectly limited, distinct from all others, not only in its own substance, but in its mass and its mode of motion—qualities which will preserve forever. These portions are atoms. In the perfect medium which contains them all, none of them can change or disappear, none of them can be formed spontaneously. Everywhere atoms of the same kind are constituted after the same fashion, and are endowed with the same properties. It is well known, in fact, that the atoms of hydrogen vibrate exactly in the same periods, whether we heat them in a Geissler's tube, observe them in the sun or in the most distant nebula."

MEXICAN HIEROGLYPHS.—It has been recently reported that Rev. Father Damazo Soto, of Concordia, Mexico, had discovered a key to the Aztec writings. This announcement ex-

cited considerable diverse comment, as it was known that the ancient Aztec picture writing had long ago been deciphered without much difficulty. The New York *Tribune* hazards the opinion that it is the Toltec writings, and not the Aztec, to which Father Soto thinks he has discovered the key. Of the Toltec writings the *Tribune* says: "We are not aware that any of this priestly text has been deciphered fully, though enough is known of it to warrant the belief that much of the language employed conveyed an esoteric meaning, and was intended to conceal supposed truths from the eyes of the vulgar, much as alchemists used to conceal the real significance of their speculations and formulas in the middle ages. Could this Toltec hieratic writing be deciphered, it is probable that new light would be thrown upon the religion and science of that ancient and interesting people, and such information would be particularly welcome in this era of analytic inquiry."

A SINGULAR OCCURRENCE.—On the 28th of January last, during the great storm, a phenomenon was observed at Hueneme, Ventura county, which possesses some scientific interest in connection with the origin of tornadoes, or, as they are popularly but erroneously called, cyclones. Between 4 and 5 o'clock on the afternoon of the day mentioned a waterspout was observed at sea, traveling in the direction of the town. It left the ocean behind it a scething track of foam, and, "as it came nearer, water was seen whirling in it, and dark objects, either large fish, seals or hordes of seaweed." On striking the shore the waterspout changed into a tornado, tearing up weeds and small trees, and finally struck a house, which it totally demolished, the floor being carried 60 feet and dropped without harm to the occupants. A second house stood in the pathway of the terrible destroyer, but luckily the rotating air column took one of those sudden leaps upward which are mentioned in reports of so many Western tornadoes, and the house escaped uninjured. These particulars are furnished by a correspondent of the San Buenaventura *Free Press*, and show that it was a genuine tornado which did the mischief—such as abound in Kansas, Missouri and other States of the Mississippi valley—but of smaller dimensions and inferior destructiveness. But the interesting circumstance is that this tornado occurred partly on sea and partly on land, and thereby proved the absolute identity, so far as cause is concerned, of waterspouts and tornadoes as completely as Franklin's experiment with the kite proved the identity of electricity and lightning.

INFLUENCE OF HEAT ON THE MOLECULAR STRUCTURE OF ZINC.—In an article published in a foreign exchange, S. Kalscheer says that when rolled zinc is heated to at least 150° C. (302° F.), it loses its clear ring, is easily bent, produces a noise which greatly resembles the "tin cry"—that is to say, it becomes crystalline. If such a plate, that has been heated, be suspended in a solution of copper sulphate, the precipitated copper will show distinctly a crystalline structure. Accompanying this change of molecular structure there is also an increase of density, amounting to .003, that takes place; at the same time the electric conductivity is increased by 3 per cent. After strongly heating copper and iron, evidences of crystallization were clearly seen.

THE MAGNETIC TELEGRAPH FORESHADOWED IN 1625.—M. H. de Parville furnishes to the *Revue Scientifique* an extract from the dialogues of Galileo, from which it would appear that about the year 1625 a rumor had become current in various countries of Europe as to the possibility of rapid distant intercommunication by means of some magnetic process—a foreshadowing of the modern telegraph. This possibility is thus indicated by Sagrado: "You acquaint me with a person who wishes to part with a secret which would enable persons, by means of certain sympathies existing between magnetic bars, to communicate with each other, although removed by distances of two and three thousand miles."

A MINIATURE INCANDESCENCE LAMP.—A small incandescence lamp for philosophical purposes has been introduced by Mr. J. C. Fuller, of Finsbury Pavement. The electrodes are zinc and carbon, and the fluid a solution of bicarbonate of potash. The cells are stated to remain active for more than thirty hours, and the expense of fresh fluid is said to be about threepence.

ELECTRO AND ORDINARY MAGNETS.—The distinction between the two kinds of magnets, briefly stated, is that in the permanent magnet the amount of magnetism is fixed, whereas an electro-magnet remains magnetic only when a current is passing round it—except that it acquires by the process a small amount of permanent, or what is called residual magnetism.

PRIZE FOR AN ORIGINAL ESSAY ON SANITARY SCIENCE.—The Worshipful Company of Grocers, of London, have issued an announcement, offering a prize of \$5,000 for the best essay on the above subject. This prize is awarded every four years, and is open to universal competition, British and foreign.

A SCIENTIFIC Convention is to be held in Philadelphia next year, made up of American Scientists, and a local committee has been organized to extend a generous welcome to the visitors.

TABLE OF CONTENTS.

EDITORIALS.—Cornish Roll Grinder; Academy of
Sciences; Mining Claims in Canyons, 136. Passing
Events; Gypsum on the Pacific Coast; Quicksilver
Flasks; Nitrate of Soda; Mines in Unnavigable Streams,
139. The Worthington Pumping Engine; Change in
Mining Systems; Our Mineral Resources, 140.
ILLUSTRATIONS.—Grinder for Cornish Rolls in
quartz mills; Rear of Grinder for Rolls of Quartz Mills,
136. The Worthington Compound Pumping Engine,
140.

CORRESPONDENCE.—Disturbances of the Ameri-
can Continent; White Oaks, New Mexico, 136.
MECHANICAL PROGRESS.—Improvement in the
Bessemer Process; Unsolved Problems; Steam Boil-
ers; American Steam Mills the Best; Scrap Forgings;
A Remarkable Steam Engine; The Diamond Drill as an
Excavator, 137.

SCIENTIFIC PROGRESS.—The Automatic
Theory; Mx in Heredity; A Singular Occurrence;
Influence of Heat on the Molecular Structure of Zinc;
The Magnetic Telegraph Foreshadowed in 1825; A Mini-
ature Incandescence Lamp; Electro and Ordinary Mag-
nets; Prize for an Original Essay on Sanitary Science,
137.

THE ENGINEER.—A Fireless Locomotive, A New
Idea; Modern Engineering; Simple and Compound En-
gines on Short Routes; The Nicaragua Canal Project,
141.

USEFUL INFORMATION.—Horse-Power of
Boilers; Wire Rope Splitting Out Granite; Canal Rail-
road; Locomotive, 141.

GOOD HEALTH.—How a Man Drowning One Thou-
sand Feet Feels; Border-Land of Insanity; The Best
Remedy; A New Mode of Burial; Copper and Lead in
Food; Danger at the Grave; Dandruff; Died from Eat-
ing Wild Parsnips; Eat Salt with Nuts, 141.

MINING SUMMARY.—From the various counties
of California, Nevada, Arizona, Idaho, Montana, New
Mexico, Oregon and Utah, 143-44.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Meetings, Assess-
ments, Dividends and Bullion Shipments, 145.

MISCELLANEOUS.—Colorado Mining Outlook;
Mining Ditches and Irrigation, 136. Publication of
Mining Notes; Quicksilver Mining in California; The
Camar d'Alencas; Water-Gas Furnace, 140.

Passing Events.

The severe storms and floods in Southern Cal-
ifornia and also in the great valley are some-
what phenomenal. The idea of rivers and
streams in Southern California overflowing
their banks, bridges being washed away, and
water washing around freely, seems strange.
As a general thing the complaint is of dryness.
But now the waters are out and trains cannot
pass, the passengers for Los Angeles having
been brought back here by the railroad com-
pany and sent down by steamer. There have
been floods and cyclones in the East, and cold
weather has prevailed everywhere.

The "Camar d'Alencas" boom seems to continue
without abatement, and many miners are
preparing to go there at as early a moment as pos-
sible. We have been gathering all the news
possible concerning the country for those of our
readers interested.

The mines at INL, Nevada, have never
looked better, and several claims at that camp
are daily turning out a small amount of very
rich ore, which is being sacked and shipped to
San Francisco.

The copper mines at White Cloud, Nevada,
have been sold for \$30,000, and in all probability
that canyon will have as large a smelter as is
in the State running there before next fall.

Gypsum on the Pacific Coast.

Gypsum has been discovered at many points
in California, Arizona and Nevada. The heav-
iest deposits of this mineral which have been
found in this State are in Los Angeles county,
where it occurs in beds scattered along the foot-
hills from Caliente to Long Tom, a distance of
20 miles or more. The deposits here seem to
be of good quality and abundant. Small hodies
of gypsum have been found at many points in
the Coast Range to the north of San Francisco,
and in various other parts of the State. A de-
posit of the variety known as selenite occurs
near Stockton, and within a few miles of the
San Joaquin river. Heavy beds of gypsum oc-
cur in Nevada. This mineral is also abundant
in many parts of Arizona. The gypsum-bearing
localities of that Territory are: On the car-
boniferous formations of Yavapai county, de-
posited in thin horizontal sheets; east of the
Rio Verde, about 35 miles north of Camp Me-
Dowell; in the pine country east of the Verde
settlements; on the south side of the Gila
river, 25 miles from San Carlos, Pinal county,
abundant and very white; in the Chiricahua
mountains, southwest from Cabeza Peak and
nearly due south of the Apache pass, on the
headwaters of the San Pedro, near to, if not
over, the Mexican line; on the plains of Yuma
county, 35 miles southeast from the Vulture
mine, in Mohave county, 18 miles northeast
of the Santa Maria placers. Prospectors re-
port deposits at other localities than those
named by Mr. C. P. Stanton, in "William's
Mineral Resources."

About 12 years ago the manufacture of plaster
from gypsum was begun in at the Golden Gate
Mills, in this city, where the business has been
continued ever since. The plaster sells here at
about the following rates per barrel: Hard for
finishing and general use, \$2.75; for casting
ornaments, medals, etc., \$3; superfine, for
sculptors' use, \$3.50; these being about 20
per cent less than the prices paid for the im-
ported article. Common plaster, now beginning
to be found extensively in California for use as
a fertilizer, sells at a rate of about \$12.50 per
barrel.

Notwithstanding that the crude material is so
abundant in California and adjacent regions,
most of the gypsum ground into plaster here is
imported from abroad. The imports at the
port of San Francisco, for the past 10 years,
have been as follows:

Year.	Bbls or Cskts.
1874.....	19,176
1875.....	22,782
1876.....	14,918
1877.....	14,487
1878.....	11,039
1879.....	5,408
1880.....	3,200
1881.....	3,285
1882.....	4,777
1883.....	1,203

This is imported as "plaster-of-paris." The
diminished importations of late are due to the
considerable product made by the mills in Cal-
ifornia. The principal use to which gypsum is
devoted is an agricultural one. The ground
rock or land plaster is applied as a top-dressing
to the soil, and although it does not enter to
any extent into the composition of plants, it has
still an extremely beneficial action upon plant
life and growth, from the chemical changes
which it induces in the soil. Stucco, plaster-
of-paris, or calcined gypsum, is used for making
cornices, frezes and other forms of interior de-
corations, and its use in making walls them-
selves is increasing. A fine grade is used in
taking casts of natural objects, making models,
etc.

ARIZONA COAL FIELDS.—The bill introduced
by Senator Miller of California to segregate the
Deer Creek coal fields of Arizona and open
them up to settlement is being antagonized by
Commissioner of Indian Affairs Price. Miller's
bill provides for the segregation and sale of the
coal lands to original locators at \$5 per acre.
Indian Commissioner Price desires to lease them
to Arizona speculators, believing their use
could be made a source of revenue on a royalty
of ten cents per ton for the coal extracted.
There being no precedent for leasing such lands,
Price's proposition is very unpopular among
Congressmen whose attention has been called to
it. Secretary Teller was before the sub-com-
mittee of the House Committee on Public Lands,
to whom the original bill was referred in the
House, and expressed himself as being in favor
of allowing the original locators to purchase,
and upon his statement the sub-committee has
agreed to report favorably. These coal fields
are located upon the White Mountain Indian
reservation and are very valuable. The original
locators, who are mostly miners, have been
holding them for several years against the op-
position of a very large party of speculators who
are endeavoring to possess them. Their opening
would reduce the price of coal for milling in
Arizona fifty per cent and many representatives
of Arizona miners are pushing Miller's bill.

Quicksilver Flasks.

The flasks in which quicksilver is marketed
and conveyed to the gold and silver reduction
works, etc., are made of wrought iron, and are
sent to California from Pennsylvania. New
flasks cost \$1.25 each, and old ones are
worth from 75 cents to 90 cents. They are
quite uniform in dimensions, shape and appear-
ance, and no patented forms have come into
use. Many people around mills and mines like
to "guess" at sizes and weights of these flasks,
and picking up a full one is sometimes con-
sidered rather a test of strength. The average
weight of an empty flask is 13 pounds, and each
will hold 76½ pounds of quicksilver. In the
regular type the flask is cylindrical, with a
small conical top, and the extreme length inside
is 11½ inches. The mouth is one inch, tapering
to ¾ inch at the neck. At the sides the inside
length is 11½ inches, and the inside diameter is
4½ inches at the bottom, 4½ inches at the mid-
dle, and 4½ inches at the top. The flasks are
¾ inch thick at the top, ¾ inch at the bottom,
and three-sixteenths of an inch at the sides of the
shell. For convenience in handling in trans-
portation by stages and wagons the flasks are
sometimes enclosed in leather jackets provided
with handles.

The well known trade mark "A," on top of
the flasks containing quicksilver from the
largest mine in the country, the New Alma-
den, in Santa Clara county, is secured by U.
S. patent, and registered. These flasks contain
76½ pounds of quicksilver, but foreign quick-
silver is sold in flasks containing only 75 Span-
ish pounds, equal to 76.07 pounds avoirdupois,
or 43-100 of a pound less than is contained in
flasks of "A brand." Foreign-made flasks are
undersized, badly made, and not fit for second
use. The "A brand" Quicksilver is put into
American flasks, which, when empty, can be
sold for 75 cents each.

The advantage is largely in favor of pur-
chaser of American quicksilver at equal price:

100 flasks American contain surplus, 43 lbs., at 36 cents a pound.....	\$15 48
100 flasks, empty, 75 cents each.....	75 00
Total.....	90 48
100 Spanish flasks, old iron value, 12 cents each.....	12 00

On 100 flasks, gain by purchaser of American
quicksilver..... \$78 48

The weight and purity of the product is
guaranteed, and the present price is \$29 per
flask.

Desilverizing Poor Argentiferous Lead.

The desilverization process of poor argentifer-
ous lead by the Corduric-Schnabel process in
the metallurgical works of Lantenthal, is car-
ried on, as described by the *Berg und Hütten-
manische Zeitung*, which we translate, as fol-
lows:

The alloy which is obtained by the desilveri-
zation of poor argentiferous lead (werkblei),
consisting of a zinc-lead-silver alloy, was, ac-
cording to Flaeb's process, melted together with
the basic slags in a furnace, and has given the
following results: Silver, 102.4520 per cent
against the assay; lead, 96.3415 against the
assay. The method of Corduric, which con-
sists in treating the alloy with steam, and in
submitting the remaining mixture of rich argen-
tiferous lead and oxides to a furnace, oxydation
process (*abtrennung*) yields: Silver, 104.4812 per
cent, and lead, 98.8904 per cent, against the
assay.

The combination of Corduric with Schnabel's
ammonia process consists in desilverization of
the poor argentiferous lead (werkblei) by means
of zinc, in the decomposition of the resulting
lead-zinc-silver alloy by steam, and extraction
of the oxide of zinc by ammonium carbonates,
and separating in the mixture, free from zinc,
the silver from lead, as before mentioned.

By this process, the entire amount of the
oxide of zinc is transformed into carbonate of
zinc, and regained as a by product. From the
year 1879 to 1882 an average of 105.669 per cent
silver and 99.2081 per cent lead against the
assay was yielded. Subtracting from these
figures the so-called "allowance" which is al-
lowed in favor of purchasing ores, as follows:
4 per cent loss of cupellations, 1.6 per cent, not
counting fractions 0.5 per cent, overweight, or
together, 6.1 per cent, the real yield of the sil-
ver will be 99.56 per cent. For the lead the
difference between assay and analysis 2.5 per
cent, overweight 0.50 per cent, total 3.0 per
cent, the real yield for the lead will then be
96.2081 per cent. The proceeds of the sale of
zinc carbonate covers as well the expenses of
the Corduric-Schnabel process, and leaves a
plus of 15 per cent to pay interest for the
capital put in.

Nitrate of Soda.

Occurrences.

Slight deposits of this salt (Chili saltpeter)
have lately been found in Humboldt county,
Nevada, the site of this "fud" being located
on what is known as the "Forty-mile desert"
and at a point about 25 miles east of Lovelocks
Station, on the Central Pacific railroad. This
salt occurs here in a crystallized form, deposited
in the crevices of the rocks, also imbedded in
the earth from 2 to 30 inches below the
surface. As the deposit at this point has not
yet been much developed, nor the district
about even thoroughly explored, how much of
the mineral exists here is unknown. As the
geological and climatic conditions of this
region greatly resemble those about the district
of Tarapaca, near the northern frontier of Chili,
in Peru, where the dry pampa for 40 leagues is
covered with a bed of this salt several feet
thick, it may reasonably be expected that this
valuable mineral will be found on these desert
lands of Nevada, in considerable quantity.
Here, as at Tarapaca, the nitrate of soda occurs
in an arid and almost rainless region, the
annual rainfall on this Nevada district amount-
ing to scarcely more than 4 inches, while on
the coast of southern Peru it is still less.
both localities occupy what was once the bed
of the ocean or inland sea, both have about
the same mean temperature and elevation
above tidewater, and on both are found in
heavy deposits of common salt, the sulphates
of lime and soda, magnesia, alumina, etc.,
some of the borates of lime and soda being also
found in the Nevada field. An organization
known as the Nevada Niter Company has
taken up an extensive tract of land covering
what is considered the best of these Nevada
deposits, with the purpose of exploring and
utilizing them, should enough of the crude
salt be found to warrant their doing so. In
April, 1833, a deposit of nitrate was found near
Calico, San Bernardino county, California.
Fine samples were sent to San Francisco for
examination. As yet, however, the extent of
the deposit is undetermined, and no operations
tending to its development have been com-
menced. The Central Pacific railroad carried
eastward from San Francisco 64,640 pounds of
nitrate in 1882.

Nitrate of soda is said to occur in the extreme
southern portion of New Mexico in considerable
quantity. It is deposited here by a few springs,
the greater number being in Chihuahua,
Mexico, just across the boundary line. No
disposition is made of the product, beyond the
shipment of a limited quantity to Chihuahua
by Mexicans. The following table shows the
imports and exports of nitrate of soda during
recent years:

IMPORTS AND EXPORTS OF NITRATE OF SODA.			
Fiscal years.	Imports (speci- cally valued; free of duty).	Exports.	
		Quantity —Lbs.	Value.
1872.....	\$928,079	3,100	\$124
1873.....	1,452,730
1874.....	1,338,141
1875.....	903,615
1876.....	1,055,360
1877.....	1,823,457
1878.....	979,322
1879.....	1,348,572	91,940	2,988
1880.....	1,805,110	153,936	5,773
1881.....	2,356,183	10,564	370
1882.....	a 3,911,545	429,988	14,435
Calendar year 1882.....	b 3,045,127

a Quantity imported, 184,534,374 pounds.

b Quantity imported, 150,297,385 pounds.

Mines on Unnavigable Streams.

Ever since mining was first commenced on
this coast, people have moved on the small un-
navigable streams where gold was to be found.
Yet, no less a personage than the Commissioner
of the General Land Office recently suggested
on deciding to cancel an application for a patent
to a mining claim, that "it is against the public
policy to allow placer mining in the beds of un-
navigable streams, and that the patentee would
obtain a right to and control over the water."

The Secretary of the Interior very promptly
remarked on overruling the decision: "It is not
necessary to discuss these points at length, I
think. It is well settled that if the beds of un-
navigable streams contain mineral deposits,
they may be appropriated for mining purposes,
and that, as to the water, the locator obtains
only an usufruct in it."

The claim was on Bear River, a very small
unnavigable stream in this State, winding
through canyons with precipitous banks, where
there have accumulated extensive placer
deposits. Some official will be declaiming
before long that miners have no rights that the
other people are bound to respect. Talking
about it being against public policy to work
placers in the little mountain streams, seems
nonsense. No richer deposits of gold ore was
ever found than those on the old bars of our
rivers in the early days.

The Worthington Pumping Engine.

Several forms of the Worthington pumps are made adapted to various purposes. The engraving on this page shows the "compound" type. This arrangement is intended for using steam expansively, which cannot be done in the ordinary form. The steam having exerted its force through one stroke upon the smaller steam portion, expands upon the larger during the return stroke, and operates to drive the piston in the other direction. This is, in effect, the same as using a cut-off on a crank engine, only with the advantage of uniform and steady action upon the water. It is recommended in any service where the saving of fuel is an important consideration. In such cases its greater first cost is fully justified, as it requires 30 to 33 per cent less coal than a high-pressure form on the same work.

A modification of this style, larger and with condenser, is used for public water works. As an evidence of the care with which this class of engines is constructed, the statement of Mr. Lawrence, President of the Charlestown (Mass.) Water Works, is cited in having said "that the cost of repairs for six years was \$100 on two pumps having a capacity of five millions of gallons a day each." Mr. A. L. Fish, the agent of these pumps for this coast, gives us some additional particulars in the form of the statements of experts as follows:

The late Alexander L. Holley, mechanical and civil engineer of Brooklyn, New York, who was consulting engineer for the Bessemer Steel Works, Troy, the Cambria, the Bethlehem, the Joliet and other iron works, made under oath a statement concerning the Worthington system of pumps, from which we make the following notes: In all Bessemer works, pumping engines for throwing large volumes of water under heavy pressure—300 to 400 pounds per square inch—are required to actuate cranes, hoists, converters and other hydraulic machinery. The hydraulic machinery is the most expensive and the hardest worked part of the plant; and the constancy and steadiness of the pumping power is the most vital feature of the whole system of machinery. Any delay or serious fluctuation in its operation in handling fluid masses of iron and steel, is fatal to the commercial success of the Bessemer process. In all these works, when in full operation, the pumping engine runs from twenty to twenty-four hours per day, rarely excepting Sundays. The strain on the engine is constant, but the velocity is momentarily and suddenly varied by the demand for water, from a low to the highest speed. Yet the pressure on the cranes, etc., is, and for safe working must be, nearly constant. The heavy pressure, by itself, puts the machinery under a severe stress; but when this pressure is also associated with great volume, requiring very large parts, the conditions of service are more severe than any others with which I am acquainted. After an extensive acquaintance with the Worthington engine, and with all such other forms of pumping engines as have been applied to the purposes mentioned, I have adopted it exclusively; and, to my knowledge, it is adopted in every Bessemer works running or building in America. I consider it, in the present state of art, indispensable to safe and regular working; and I believe that we should suffer more damage from break-downs and from delay in carrying on the conversions, by dispensing with this engine than by dispensing with any other improvement in the Bessemer plant.

The reason why this pumping engine stands this severe service without extraordinary repairs, and the reason why it imposes an extraordinary stress on the machinery it actuates, is, that the system on which it is constructed—the movement of the steam valve of one engine by the piston of the other engine—permits the water pistons to stop momentarily at the ends of their stroke, thus allowing the water valves time to seat without slamming; all this being associated with a uniform velocity of piston, and hence a uniform pressure on the water pumped, instead of a varying pressure, such as is caused by an irregularly moving piston attached to a fly-wheel. The water flows through the Worthington pump, and to the cranes, in a constant and noiseless stream. In all other pumps with which I am acquainted, when applied to such service, there is violent concussion of the water, slamming of the valves and jarring and straining of all parts, and consequently, frequent break-downs of the pump and of hydraulic pipes and machinery. I have also, for the same reasons, adopted the Worthington pump, after extensively comparing it with various other pumps for feeding boilers; and I find its advantages very marked, although not so conspicuous as in the service above described.

Two experts, J. Herbert Shadd and John F.

Ward, reported to the city of Buffalo Water Commissioners, the following facts concerning trials of these pumps at Buffalo:

In accordance with the request of both parties to your contract, dated the 18th day of November, 1880, the experts appointed under that contract report, in addition to their formal report of the 6th instant, as follows:

The engine was run uniformly, for determining duty, from 10:30 A. M. to 10:30 P. M. of the 12th of January, 1883. The number of gallons displaced in that time was 9,661,321-1000, or say 19,323,365 gallons per day of twenty-four hours. The contract required a delivery of fifteen million gallons of water in twenty-four hours of 77.6 per cent only of the quantity actually displaced, or in other words the displacement was 24.8 per cent greater than the required delivery.

The average pressure above the delivery valves, against which this quantity of water was pumped, was 74.90 pounds. The pressure required by the contract was 70 pounds, or 93.46 per cent of that attained during the trial. In addition to this, the engine worked against a lift of 19 feet from the surface of water in the pump well to the delivery valves. The contract required that 70,000,000 pounds of water be raised one foot high with the consumption of 100 pounds of coal. The duty performed by the engine, as reckoned from the average of the steam cards, taken at intervals during the trial, and based upon the terminal pressure in the high pressure cylinder in the usual way, was 78,319,545 foot pounds, or 11.72 per cent above seventy millions. The duty based upon the cards at cut-off, which could not be so accurately determined, was a little over seventy-nine million foot pounds.

At the request of the water commissioners, an extra pressure was put upon the force main

THE WORTHINGTON COMPOUND PUMPING ENGINE.

of the engine, after the trial for duty, and for nearly an hour the engine ran steadily, and pumped directly into the high service distribution against an artificial pressure of 80 pounds per square inch above the delivery valves, and held that pressure with remarkable regularity throughout the run. So far as could be seen, this pressure might be held indefinitely.

The engine is of excellent material and workmanship, and is larger than the contract requires. The net displacement per count is 972.09803 U. S. gallons, or 129.9506 cubic feet. The average number of counts per minute during the trial was 13,8042.1000. The number of plunger displacements in twelve hours was 39,756, and the total amount of shortages observed would be made up by the running of the engine about one-twenty-third of a second, a period of time much too small for notice. The number of observations made during the time when shortages were observed was 1368, and if we assume that in the unobserved strokes the same ratio of shortages occurred, then the whole amount of shortages occurring in twelve hours would be made up in running 1 1/2 seconds, an amount still too small for recognition in the records of the engine as taken by the observers. This shows that ten-thirty-fourths of one revolution makes up all loss at end of cylinders during twelve hours' trial.

A GENERAL STRIKE of the Pittsburg railroad coal miners against a reduction of half a cent is looked for shortly. The ruling rate is 3 1/2 cents, but in a number of instances the operators refused to pay more than 3 cents, and they claim they are unable to run pits at a profit and pay the former rate.

THE new reduction and concentrating works at Corbin, Montana, have been completed. These are said to be very complete, probably the best plant of the kind in that Territory. The estimated cost is \$60,000 and the capacity 125 tons every 24 hours.

Change in Mining Systems.

The substantial product of the Tombstone mines during the past two years, says the *Epitaph*, must stand as very strong evidence in regard to the real value and true worth of property and practically conducted mining operations, and will stand as a monument of unquestionable solidity which will doubtless do much toward establishing confidence in the permanence and profitability of our mines.

Since the earliest history of mining, new discoveries have always created more or less excitement, and for a time the value of the mines has been overrated; then would follow a season of depression; many would find that they had allowed their impulses and speculative ideas to so far govern them that they had blindly and unwittingly invested money where there was no hope of return. Mining operations carried on under the management of practical and competent men prove to the world by their substantial output of bullion, the true merit of mines. Then may be seen indications of returning confidence. And as people, through experience, learn to discriminate between the real and fictitious, and this confidence, which has been so cruelly betrayed by unscrupulous men, will be re-established and become permanent and universal. This has been the case at Tombstone, but to-day the age of impulse and speculation is a thing of the past, never to be repeated, and the great mineral deposits of our country are now regarded as fixed facts, and as treasures which may be secured by wisely developed plans, careful and practical management, and that persistent energy by which man wins all his success from that with which the bountiful hand of nature

Our Mineral Resources.

(WEEKLY REVIEW.)

The metallic domain of the United States, developed and undeveloped, is unsurpassed by any territory of the same area in the known world. We do not realize its magnitude, great value and extent, and can only estimate ourselves, without boasting, that a nation we are not only self supporting, but formidable rivals in many branches of this industry, and only second to Great Britain is the two great staples of coal and iron. Our veins, beds and deposits are diversified, and as yet comparatively virgin, comprising all of the minerals and metals known to man in apparently unlimited quantities. New discoveries of mines of fabulous richness are being made much more rapidly than earlier finds are exhausted, and the mineral portion of the territory of the United States is constantly being extended by new finds. As metal and mineral producers we have by no means reached the maximum of our producing power. We have in the brief history of our national life reached a productive standpoint that has astonished and revolutionized the world.

It is estimated that the annual production of the United States is equal to one-third of all the gold and one-half of all the silver produced by the whole world; that we are a formidable factor it is universally acknowledged, as evidenced in the coinage laws of nations which are compelled to conform to our production. Hon. H. C. Burchard, Director of the United States Mint, estimates the total production of our mines to June 30, 1883, as follows: Gold, \$1,632,364,670; silver, \$398,083,217; total, \$2,230,447,887. The year 1884 will no doubt show a considerable falling off in our gold products—California being the principal producer of this noble metal—owing to the recent decision of Judge Sawyer, adverse to the prosecution of this industry. The miners consider there are good grounds for believing, however, that this unfortunate decree will be reversed by the Supreme Court of the United States on appeal; and that his enjoiner virtually putting a stop to gold mining in certain parts of the State will have but a temporary effect, as we have not by any means reached the maximum of our gold-producing power. To destroy this industry or even check it, would be a great misfortune, for to it to a great extent we owe our present status. In this connection we do not ignore our agricultural interests, which have also been an important factor in our prosperity. But we have reason to fear that our main staple, wheat, of which we have produced and exported so largely, is no longer king, and like King Cotton which once reigned supreme in the Southern States, was deposed by a foreign production which supplied the foreign demand. Our consumption here is limited, and our Eastern brethren furnish more than enough wheat for their requirements. Consequently, without a foreign demand, we have no market for our surplus. From recent advices, it is believed that not only Russia, but India and the Persian Gulf have come to the front as large and increasing producers in this staple—as through the assistance of increased railroad facilities and cheap labor, the cost of production here is considerably less than in any other part of the world.

The following data, however, is suggestive of the values of this industry. The enumerated mines are but a small proportion of the many in California that are in actual operation.

A PART OF CALIFORNIA'S PRODUCTION FOR THE YEAR 1883.			
	Net	Gross	
	Dividend (2 mos.)	Product.	
Sierra Buttes, S. Co.,	\$1,250.00	212,018.00	
Plumas Eureka, P. Co.,	110,425.00	418,159.00	
Keystone, A. Co.,	230,630.00	461,975.92	
Padre & Empire A. Co.,			
from Dec. 29 to Jan.,	50,000.00	841,459.00	
The dividends approx.			
Standard, Bodie,	325,000.00	1,155,181.83	
Idaho, N. Co.,	31,100.00	362,000.00	
Summit, K. Co.,	58,100.00	120,010.00	
The dividends approx.	\$1,250,115.00	\$2,301,131.37	
North Bloomfield (Hydraulic) paid accrued bonds,	223,773.00		
Cash dividend,	180,000.00	506,199.53	
Milton,	78,548.18	278,923.11	
	\$1,721,442.18	\$4,286,061.04	

Or a net profit of \$1,700,442.18. The total haulion yield of the Milton mine up to Jan. 1, 1884, has been \$3,412,509.84.

However, with a reversal of Judge Sawyer's decision or Congressional aid, we will, no doubt, return to our usual prosperity with a largely increased output of the precious metal, as in addition to our hydraulic and drift mines, Milton.

The profits, as shown, for this company was realized from Jan. 1, 1883, to June 18, 1883. Since then no work has been done, owing to the action of the Milton dam.

(CONCLUDED ON PAGE 142.)

THE hydraulic miners are not letting the water run into the streams during the heavy storms prevailing for fear of adding to the flood in the valleys, but are catching and storing it in the reservoirs as usual. It will be allowed to flow down later in the season when there is less water in the streams.

ON pay day at Butte, Montana, some \$300,000 was paid out by the mining companies. The Anaconda alone paid \$120,000, and the Lexington, Colorado, Alice and Montana all put out big sums. Any camp where half this sum is paid for mining expenses ought to be very prosperous.

It is thought that fully \$800,000,000 has been produced by hydraulic process in this State.

Publication of Mining Notices.

The following circular has been issued to Registers and Receivers by N. C. McFarland, Commissioner of the General Land Office, Washington, D. C.

Gentlemen:—Your attention is called to the following extract from the decision of the Hon. Secretary of the Interior, in the case of Charles K. Miner, claimant of the Spencer lode, vs. J. G. Marriot et al., claimants of the Tabor lode, dated January 4, 1884:

"Section 2325 of the Revised Statutes requires, among other things, newspaper publication for the period of sixty days, as notice of application for mineral patent. It also provides that 'if no adverse claim shall have been filed with the register and receiver of the proper land office at the expiration of the 60 days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists.'"

"Section 2325 prescribes the method of procedure 'where an adverse claim is filed during the period of publication.'"

"For the purpose of deciding the question raised by the appeal, it is only necessary to apply the provisions of law above cited to the facts relative to publication, as disclosed by the record."

"These are found to be as follows: The first publication for the Tabor lode was, as already stated, on the 1st of June, 1882. The adverse claim of Miner was filed on the 3d of August, 1882."

"Excluding, in accordance with a long established rule of the department, the first day, we find the 3d of August to be the 63d day of publication."

"An apparently plain and simple proposition is thus presented for consideration."

"The law requires that an adverse, to be effective, must be filed within the sixty days of publication. Miner's adverse claim was not filed until the sixty-third day. Was it filed within the period prescribed by the law, and has the adverse claimant a legal status as such?"

"This would admit of no discussion except the following facts: This department has held for a number of years (certainly since 1874) that where publication is made in a weekly newspaper, ten insertions are essential in order to show compliance with the law requiring sixty days' publication. In such cases the tenth issue falls on the sixty-third day after the first. In view of this ruling of the department, your office in October, 1879, promulgated a decision or order containing the following: 'The last, or tenth, insertion being essential, it follows that adverse claims may be filed until the expiration of the day upon which the last issue of such weekly publication is made.'"

"This rule has since been followed by your office and you therefore recognize as legal and valid the adverse claim of Miner, filed on the day of tenth issue of paper containing publication, &c., on the sixty-third day. In my opinion, the practice of your office referred to is not necessary as a logical result of the rule requiring ten insertions in a weekly paper, nor is it consistent with the law which prescribes the time within which an adverse claim may be filed."

"Section 2325 of the Revised Statutes specifically fixes sixty days as the period of publication, and says, 'If no adverse claim shall have been filed at the expiration of the sixty days of publication it shall be assumed that the applicant is entitled to a patent,' etc. The regulation requiring ten publications (in a weekly paper), thus in fact making the period sixty-three days instead of sixty, does not alter the law as to sixty days for the filing of an adverse."

"The regulation has its reason in the fact that in no other way can the law requiring sixty days' publication be complied with. Nine issues of a weekly paper would not cover the required period. It is true that the tenth insertion carries the publication three days beyond the legally required sixty days, yet for the purpose of meeting the requirement of law ten insertions are in fact necessary, since the contingency for sixty days can be preserved only by the tenth publication which falls on the sixty-third day after the first. It is also true that the applicant cannot proceed to complete his entry until the tenth publication, but this is because it is essential as proof of sixty days' publication. These reasons do not apply to an adverse claimant, and his acts are not controlled thereby. He has the plain letter of the law for his guide. His course is clear and his duty plain. He has sixty days, on any one of which he may file an adverse claim."

"If he fails to file within the sixty days of publication prescribed by the law, then he is barred."

"So far as he is concerned the question is one of simple computation."

"It would be equally plain as to the applicant except for the reasons herein given, and which do not control in considering the rights either legal or equitable of an adverse claimant."

"So far as the case under consideration is concerned, however, your decision that an adverse claim was properly received, and therefore dismissing the appeal, is affirmed. The rule of this decision should not operate to interfere with or take away any rights acquired under the law as it has heretofore been con-

strued by your office. Though that construction is, in my opinion, clearly erroneous, such fact does not render illegal any acts which have been performed in accordance with and pursuant to that construction or interpretation. Until a rule is changed it has all the force of law, and acts done under it while it is in force must be regarded as legal. This view will govern you in the consideration of any similar cases which may arise."

After the receipt of this circular at your office, you will be required to observe strictly the above ruling of the department."

Quicksilver Mining in California.

The following item, which appeared in the *Sau Jose Mercury* a few days ago, we found floating the round of the press:

The quicksilver mines in Napa and Lake counties are turning out a fair yield of that useful and valuable article. Four or five mines in that section are now being worked at their full capacity, being kept running night and day.

We thought the statement at the time exceedingly doubtful, but gave it for what it was worth, by adding the qualifying words "are said to be," etc.

Unfortunately, upon investigation, says the *Mercury*, we find the facts to be otherwise. The quicksilver mines in Napa, Lake and other counties in this State where quicksilver mines are now worked, are not turning out a fair yield, but are doing very poorly.

At the end of December, 1883, the Sulphur Banks quicksilver mine shut down, because of poor ore and extremely low price for quicksilver. In January, 1884, the Great Eastern mine, in Sonoma county, followed suit and closed its works. The *San Francisco Bulletin* of January 30, 1884, in an exhaustive article on "The Profits of Mining," says: "The Napa Consolidated Quicksilver paid [dividend] in November, and is the only quicksilver mining company in America that paid a dividend last year."

That does not look like good times for quicksilver mines—only one \$10,000 dividend for the year. This is explained by increased costs for mining, poorer ores, and the lowest price ever known for quicksilver.

We give at the close of this article a table showing the decrease in production of all quicksilver mines in this State during the last two years. It will be observed that the production for 1883 was 46,725 flasks, or 6,007 flasks less than in 1882. The average price was \$26 a flask against \$28 in 1882; the total value \$1,214,928, and divided profits \$10,000. The decrease in value of the year's production equaled \$93,456.

California cannot compete with the quicksilver mines worked by the governments of Spain and Austria. If our quicksilver mines are not protected by a fair tariff (10 per cent ad valorem present duty is too low), they must be abandoned as an unprofitable industry, and then the production of gold and silver ores in the United States will be practically controlled by Spain and Austria, for they possess the only other quicksilver mines, and as quicksilver is indispensable for working gold and silver ores, they may and no doubt will put the price of quicksilver to a point that will prohibit the working of low grade silver and gold ores.

Production of quicksilver in California 1882 and 1883.

Or Quijotoa, it is said that the bonanza firm is not making efforts to find water at the mines, all efforts in this direction being prosecuted by the townspeople. The finding of sufficient water to run mills is not looked for by the mine owners, who expect to ship their ore out by rail, it being thought that the passenger and freight traffic in the camp will more than offset the carrying of the ore out. It is thought that the point of connection with the Southern Pacific railroad will not be either Tucson or Casa Grande, but at Picacho, a station between the two.

THE SPRUCEMONT MINES.—On our way to Elko last week we met Mr. Sherff, one of the principal owners in the Spruceмонт mines, on the train. He informed us that the property was looking finely. They have already ore on the dumps to the value of \$80,000, by actual assays. They will put up a first-class furnace in the spring, and turn this ore into bullion. The prospects in the mines are now better than when they first struck ore. Mr. Sherff is a practical gentleman and not at all carried off by his present and prospective good fortune.—*White Pine News*.

The silver mines of Tombstone alone, since their discovery 4 years ago, have produced above \$15,000,000.

The Cœur d'Alenes.

A practical and intelligent gentleman, who has just returned from the Cœur d'Alenes and who thoroughly examined into the prospects of the new district, states to the *Butte (W. T.) Inter-Mountain*, without hesitating, his entire inability to come to a positive conclusion as to its future. He says that not even those who have wintered there know anything about the merits of the country, either in regard to quartz or placer. The ground is covered with four feet of snow and only one of the claims is accessible. The merits of the placers have not been demonstrated. They may be good or they may be worthless. The fact that in places good pay has been found on rim rock is evidence, but not proof positive that the bed rock will be rich. There is no use of men rubbing pell mell into the new country in mid-winter, and those who do so will come back broke and disgusted before the spring sufficiently opens to permit of mining operation. The railroad may boom the mines, but that is no evidence of anything except that stampedeers will be expected to pay their fare. It will take at least six months to tell whether there is enough gold in the Cœur d'Alene placers to justify any sort of stampede, and in the meantime conservative and sensible men will or should stay where they are.

From the Cœur d'Alene *Miner*, we take the following: As spring approaches the excitement over the Cœur d'Alene mine intensifies. From all over the land come letters of inquiry. Old miners are arriving on every train, some rushing into the mines at this season and others holding back until later. Men of every calling, trade and profession; of every class and condition; rich and poor, greenhorns and sharpers, all bent upon the one object of getting into the mines at the earliest possible moment, and feverish with expectation, stop off at this place and other stations in juxtaposition to the gold fields. Parties leave Spokane for the great Mecca every day—in stages, on foot, on horseback, in wagons and in sleighs. Hardly a week passes that some one does not arrive from the mines, and while they report everything quiet, yet the confidence in the yielding capacity of the diggings never wavers. Monday we had the pleasure of meeting S. E. Child, Esq., who left Eagle City Wednesday of last week. He has been through the Deadwood and Wood River excitements, and is capable of speaking intelligently upon the subject of mines and mining. In conjunction with his son, E. Child, he has a store at Eagle City. He has made several trips to and from that place, making Spokane Falls his temporary home. We had a long talk with Mr. Child, and in answer to questions propounded we were enabled to learn something of the mines and surroundings. From what he has observed during the past thirty days, he is satisfied that the richness nor extent of the mines have not been exaggerated.

Those in the mines look forward to a very lively spring, and the number is augmented daily by the arrival of fresh prospectors. He most decidedly advises men not to visit the mines at the present time unless possessed of means. Travel over the Trout creek route is accompanied with many hardships at the present time, most of the travel being done on snow shoes over a great depth of snow. While Mr. Child is not interested directly or indirectly with any particular route into the mines, he is satisfied by experience that the trail down the North Fork to the Mission, thence to the Post and on to the Falls is at present the most accessible. A route shorter and better than the others now in use can be constructed into the mines from Jackass prairie, via the Post and Mission. We may here add that that is the trail to which our business men contributed a short time ago. Captain Sanborn, one of the members of the company building steamers at the Post to run into the mines, states that the boats will commence running about March 1st, and that he can run them up the river within ten miles of Eagle City, and continue the trips for three months this spring. If a jam now existing at that point can be removed, steamers will be able to reach the mouth of Eagle creek.

E. J. Jones, writing to the *Portland Northwest News*, says: "Pritchard creek can be mined to advantage for 20 miles on either side. Miners who have located there this winter are making from \$10 to \$30 per day. I learned this from men just in from the mines. These, understand, are experienced miners. Men who have gone there this winter with from \$300 to \$700, and with no experience, will have some difficulty in wintering. All provisions are held at exorbitant prices and accommodations are of the poorest. There are now from 300 to 350 men at the mines, and this number is daily growing larger. At present the mountains are full of snow, and it would be simply a waste of time and energy to venture into this wilderness of prospective wealth before the 1st of April at the earliest. Forty-five miles north-east of Pritchard creek a new gulch discovery has been made, in a valley about one and a quarter miles wide and fifteen miles long. It is reported richer than the placers on Pritchard or Eagle creeks. Digging through seven feet of snow, prospectors discovered diggings going one and a quarter dollars a pan. A rush has already set in."

EAGLE CITY, in the Cœur d'Alene country, has been surveyed and the principal streets have been named Gold, Silver and Eagle streets.

A Water-Gas Furnace.

Mr. P. Barnes, of Joliet, Ill., recently read before the American Institute of Mining Engineers a paper on "A Water-Gas Furnace," at Elgin, Ill., as follows:

In a paper recently read before the Institute by Mr. W. A. Goodyear, a useful presentation was made of the subject of the production of water-gas on a large scale, by the use of a regenerative form of apparatus. By the way of supplement to that paper, a brief statement of the details of a plan which was carried out at the works of the Elgin National Watch Company at Elgin, Ill., may be of interest, although the ultimate result of the working of the producer was not successful or satisfactory.

This company had decided to build a gas works for the supply of illuminating gas to their factory, on a much larger scale than that of the petroleum works which had very successfully supplied the smaller buildings for many years, and in March, 1882, the material for a gas-making cupola furnace was purchased. A few weeks later it was decided to make the attempt to burn the gas under the steam boilers of the establishment, and a second set of material was ordered.

In July, 1882, when the writer took charge of the work of construction, it was agreed, after a study of the probabilities of the situation, to make an attempt to utilize the waste heat developed in the process for preheating the air-blast and the steam used, to the highest possible point, so that the fullest practicable limit of economy should be reached. This was believed to be the more needful, because of the obvious requirement that the gas should be furnished at the least possible cost, to meet the competition with coal fired direct under the boilers.

The material which had been purchased was utilized as fully as it could be in building two firebrick stoves, and the fire was put in a rectangular fire-box, which was attached to the stoves by short direct flues. The plans for this work were completed in August, 1882, and the furnace was set at work in February, 1883.

It was soon found that although the proposed preheating of the blast and of the steam was very fully accomplished, yet the shape which had been adopted for the fire box was not such as to secure the intense concentration of the heat needed to secure the complete fluxing of the furnace which had been undertaken. It was also found that the chilling of the slag, which was run down in considerable quantities by the steam blown in during the gas making, was so complete that it became quite unmanageable, and that it would lodge in the base of the fire box below the line of fusion, and also above this point, with so little fuel remaining in or near the masses of slag that they could not be remelted when the blast was turned on again. This action of the steam in cooling the slag was anticipated, but the trial was thought to be worth making.

A considerable quantity of gas was made in the furnace with the regenerative fixtures as first erected, the holder which had been provided for the storage of the illuminating gas being used for the fuel gas during the trials which were made. This was burned under the boilers, using simple perforated iron pipes for burners. A considerable evaporation was reached, but it was found that in order to compete with direct coal firing, even with the market price then current for coal used under the boilers, of \$5 per ton, the gas must be furnished for decidedly less than 5 cents per thousand cubic feet, even if the cost of labor, as compared with direct firing, were to be wholly omitted in making up the estimate.

The saving of the waste heat was found to be very complete, the products of combustion and the water-gas both escaping from the apparatus at a temperature very close to the boiling point of water.

It was found that the splintering of the brickwork in the lower part of the fire box, due to the removal of the very stubborn clinkers which were formed, would lead in any event to a very short life of that part of the apparatus as then constructed, and in view of some other important local reasons it was considered advisable to abandon the regenerative fixtures, and the expectation of using the gas under the boilers. The furnace was then rebuilt and fitted up for making illuminating gas only, upon the plan which had been used for some years in Chicago under the patents of Mr. T. G. Springer. The whole was put into very successful operation in July, 1883.

MR. ROBERTSON, superintendent of the jute mills in East Oakland, has just received three sack sewing machines from Dundee, Scotland, and is setting them up in the mills. They are the first that have ever been introduced into this country and are very expensive. They cost about \$1,300 each in Scotland, and laid down here including duty and freight will cost in the neighborhood of \$1,500 each. The mills are running on full time now with over 350 employees, and owing to the pressure of work and the immense orders on hand are running until nine o'clock at night, three times a week. In addition to the manufacture of sacks, the company is turning out a fine quality of matting and stair carpeting, manufactured from jute,

THE ENGINEER.

USEFUL INFORMATION.

A Fireless Locomotive—A New Idea.

Mr. Hougman, says the *London Engineer*, constructs an engine in which the steam is supplied by evaporation from a charge of water which is furnished to the boiler at the station, and there brought up to the required temperature and pressure. The shell of the boiler is surrounded by, or may inclose, another vessel, between which and the boiler a narrow space is left, which is filled with caustic soda. The exhausted steam is discharged into this mass of soda, which at once absorbs it, and the absorption gives rise to a large amount of heat, which is in turn given out, and returned to the water in the boiler, where it produces an additional quantity of steam; and the latter, being exhausted into the compartment containing soda, gives rise to additional quantities of heat; and thus the process is continuous, and the locomotive continues to exert its power, until the solution of soda becomes so far saturated that it can no longer take up the exhausted steam and supply heat to the boiler with sufficient rapidity to enable the engine to do its work. When this state of affairs is reached, the engine is recharged, and is again sent out on the line. The soda removed from the exhausted engine is placed in an evaporator and deprived of its moisture, and is then again ready for further service. This seems to be the first attempt to make practical application of the new well known principle discovered by Faraday sixty years ago, and probably even earlier known on the continent of Europe.

MODERN ENGINEERING.—The new harbor of Trieste, which has lately been finished with great ceremony, is a remarkable piece of modern engineering. It has taken fifteen years' work, and has cost over \$7,000,000. It consists of nearly two miles of quays, arranged to inclose three basins of eighty five acres of water surface, and these are protected by a 3,600 feet long seawall, running parallel with the shore and 1,000 feet from it. The work has been one of enormous difficulties, because of the unstable bottom, and it is stated that the walls, when once under way, sank gradually for a year, then suddenly slipped forward and out of sight. But the present walls have already withstood two of the greatest gales known in this century. The importance of this work to Austria must be very great. It is the chief seaport of the country, it has a large mercantile navy, and its exports foot \$50,000,000 a year, and its imports \$70,000,000. But its little harbor, constructed by Maria Theresa in the last century, has been entirely inadequate to its steadily growing commerce. No vessels of more than three hundred tons burden could come to its quays, and though larger craft could find generally safe anchorage in the outer roadstead, they have been exposed to danger from southerly storms. The new piers now make it possible for vessels of any size to find safe shelter in the harbor of Trieste.

SIMPLE AND COMPOUND ENGINES ON SHORT ROUTES.—Mr. Boulvin has determined a series of formulas expressing the relations between size of vessel, weights carried and distances traversed, and the weights of the simple and the compound engine, and finds that, for short routes, the best form of engine is the single cylinder rather than the compound. He finds that for lines from twenty to sixty miles in length, as those from Dover to Calais and from Ostend to Dover, a gain of a knot an hour may be obtained by the use of the simple engine instead of the compound, in consequence of the saving in weight of machinery. On long routes the economy is on the side of the compound engine, in consequence of the saving in weight of fuel. The later practice of English constructors has been in accordance with this result, and with the principles involved in the work of Mr. Boulvin. He constructs curves showing the equations graphically, and illustrates their use by examples.

THE NICARAGUA CANAL PROJECT.—Washington dates of January 20th, say: Friends and promoters of the Nicaragua ship canal, both here and in Nicaragua, feel sore over the practical failure of that enterprise, so far as this country's control in it is concerned, and ascribe it to the selfish opposition of Captain Eads on the one hand and rival railroad interests on the other. Whatever the reason, lacks of success is evident and must be accepted as a fact. The Nicaraguans do not despair, however, of yet fulfilling their scheme of a canal, and are seeking the necessary aid abroad. Meanwhile M. de Lesseps, according to all reports, is going ahead with his ditch at the Isthmus of Panama, and that genius at digging may yet show the world how simple a thing it is to accomplish an impossibility, provided the right man sets about it in the right way.

The *Engineer* of a recent date says: The whole of the network of the Belgium telegraph will be appropriated for telephonic communications within a period of four months.

AN EXPENSIVE RAILWAY.—The underground railway system, which will soon encircle London, costs \$15,000,000 per mile.

Horse-Power of Boilers.

Strictly speaking, there is no such thing as "horse-power" to a steam boiler; it is a measure only applicable to dynamic effect. But as boilers are necessary to drive steam engines, the same measure applied to steam engines has come to be universally applied to the boiler, and cannot well be discarded. In consequence, however, of the different quantities of steam necessary to produce a horse power with different engines, there has been great need of an accepted standard by which the amount of boiler required to provide steam for a commercial horse-power may be determined.

This standard, as fixed by Watt, was one cubic foot of water evaporated per hour from 212 for each horse-power. This was, at that time, the requirement of the best engine in use. At the present time, Prof. Thurston estimates that the water required per hour, per horse-power, in good engines is equal to the constant 200, divided by the square root of the pressure, and that in the best engines this constant is as low as 150. This would give for good engines, working with 64 lbs. pressure, 25 lbs. water, and for the best engines, working with 100 lbs., only 15 lbs. water per hourly horse-power.

The standard, therefore, adopted by the judges at the late Centennial Exhibition, of 30 lbs. water per hour, evaporated from 212 for each horse-power, is a fair one for both boilers and engines, and has been favorably received by engineers and steam users; but as the same boiler may be made to do more or less work with less or greater economy, it should also be required that the rating of a boiler be based on the amount of water it will evaporate at its most economical rate.

A fault frequently met with in steam boilers is the carrying over of water mechanically mixed with the steam, which water not only carries away heat without any useful effect, but, when present in any marked quantity, itself becomes a source of danger and of serious loss in the engine. Many boilers show a high apparent evaporation in consequence of furnishing "wet steam," while practically they are anything but economical. Parties have been known to claim an evaporation of 19 to 20 pounds per pound of coal, where the highest practically possible is not over 13. Such boilers are dear at any price.

The cause of priming may be either impure water, too much water, or improper proportions in the boiler. When a boiler is found to form wet steam with good water, carried at a proper light, it is a proof of wrong design.

The amount of priming in different boilers varies greatly, and as yet there is not sufficient data to establish any definite ratio for boilers in ordinary use. The experiments of M. Hirn, at Mulhouse, showed an average of at least 5 per cent; Zeuner sets it down as approximately from 7½ to 15 per cent, while the careful experiments at the American Institute in 1871 show in cylindrical tubulars 7.9 per cent.

WIRE ROPE.—Wire rope of the same strength as new hemp rope will run on the same sized sheaves; but the greater the diameter of the sheaves, the longer it will wear. Short bends should be avoided, and the wear increases with the speed. It is better to increase load rather than speed. The adhesion is the same as that of hemp rope. Wire rope should not be coiled or uncoiled like hemp rope, but should be wound upon a reel. When substituting wire rope for hemp rope, it is well to allow for the former the same weight per foot which experience has approved of for the latter. As a general rule, one wire rope will outlast three hemp ropes. To guard against rust, stationary rope should be oiled once a year with linseed oil, or kept well painted or tarred. Running rope, while in use, requires no protection. Where great pliability is required, the center or core of wire rope is made of hemp, and small sized rope is generally made with hemp centers. Running rope is made of fine wire, and standing rope of coarse wire. Wire rope made from charcoal-made iron is fully one-fourth stronger than the ordinary rope. The standing rigging of a vessel, when composed of wire rope, is one-fourth less in weight than when of hemp.

A **TROULAR SAW** was recently sent from N. Y. to a Michigan match company, which was six feet in diameter. It has fifty-two teeth and makes 672 revolutions per minute, and is capable of making a ten-inch to twelve-inch cut with each revolution. It can saw off a forty-foot plank, therefore, in an infinitesimal portion of a minute. This is not a solid saw, but is one of the new patterns, in which the teeth are separate from the plate and can be inserted and removed at pleasure. The teeth in the sort of saw of which this monster is a specimen, are little curved bits of steel pointed like chisels at the cutting end. They fit into round sockets cut out of the edges of the saw plates, and their little chisel blades project slightly beyond the circle of the plate.

SPLITTING OUT GRANITE.—The final rupture between a rock of granite and its ancient bed is an interesting process. Let us suppose the two cuts to be made, one nearly vertical, and the

other, or horizontal one, at right angles to it, and both one or two feet deep. A series of wedges is then inserted into the openings, and a man with a heavy hammer goes along, tapping them lightly one after another. As they are driven in, the men listen sharply for the effect, the crack gradually widens, the great mass of stone begins to heave and swell under the strain, the quick ear of the expert detects the critical moment, and a simultaneous blow on all the wedges throws the monster loose. Now and then, of course, a failure is made, and the block splits in two. But the judgment of the workman is singularly correct, and the block is generally thrown out in its full integrity.

USED RAILROAD TICKETS. The number of tickets collected by a first-class railroad, in the course of the year, says the *Springfield (Mass.) Republican*, is something stupendous. Five tons of these trifling paper slips accumulate in the Boston & Albany railroad office in Springfield yearly, and yield a snug sum when sold for paper stock. The colored tickets are bundled up by themselves in neat packages, and the white ones in separate lots, the latter, of course, bringing the highest price. But there is many a slip between agent Briggs' department and the pulp-room of a paper mill; in fact, the danger of having tickets used twice is so great that those collected for several years have been allowed to accumulate in a vacant room near the roof of the company's massive granite building. Three months ago a ticket cutter was added to the road's equipment, and meanwhile one man and two boys have succeeded in chewing up eight tons of tickets. A good winter's job remains, however, at least ten tons more being ready for mastication.

LITHOGRAPH STONES.—Mr. Stuart, of Edinburgh, proposes to strengthen stones which have thus been weakened by applying to them a backing of granolithic. This material, it appears, when placed in contact with a roughened surface, adheres with such tenacity as to form, with the stone it is attached to, one solid mass. Its capacity for sustaining pressure is known to be great, and if additional strength should be required bars of steel can easily be introduced while the material is in a soft condition. Treated in this way, a lithographic stone of an inch in thickness becomes thoroughly serviceable, and will, it is said, continue so till worn almost to a film. Blocks of the ordinary thickness thus become capable of furnishing the material for two or three printing stones, while slabs that would otherwise be too thin for use can be turned to profitable account.

GOLD JEWELRY may be cleaned and be made very bright in this way: Line a small tin cup with soft paper, fill with urine suds, put the jewelry in (one piece at a time, of course), shake it about well, rinse with clear water, and dry with a piece of chamois skin.

GOOD HEALTH.

How a Man Dropping One Thousand Feet Feels.

With regard to the recent sad suicide of a girl by leaping from one of the towers of Norte Dame, Dr. Bromardell's expressed view that asphyxiation in the rapid fall may have been the cause of death, has given rise to some correspondence in *La Nature*. Mr. Bontemps points out that the depth of fall having been about 66 metres, the velocity acquired in the time (less than four seconds) cannot have been so great as that sometimes attained on railroads (e. g., 106 feet per second on the line between Chalons and Paris, where the effect should be the same), yet we never hear of asphyxiation of engine drivers and stokers. He considers it desirable that the idea in question should be exploded, as unhappy persons may be led to choose suicide by a fall from a height, under the notion that they will die before reaching the ground. Again, Mr. Gossin mentions that a few years ago a man threw himself from the top of the Column of July, and fell on an awning which sheltered workmen at the pedestal. He suffered only a few slight contusions. Mr. Remy says he has often seen an Englishman leap from a height of 103 feet into a deep river; and he was shown in 1852, in the island of Oahu, by missionaries, a native who had fallen from a verified height of more than, say, 1,000 feet. His fall was broken near the end by a growth of ferns and other plants, and he had only a few wounds. Asked as to his sensation in falling, he said he only felt dazed.

Border-Land of Insanity.

The doctrine that the border-land of insanity is a very narrow one, and that most sane people are near the line, has been extensively taught during the last quarter of a century. Now, the truth is, there is a broad line between sanity and insanity, and that "all men are mad" is not true in any reasonable sense. There are, however, a large number of persons who have an insane impulse to do some wicked deed—to kill themselves or somebody else, to jump into the sea if on a vessel, to throw themselves from a height if on top of a building or on the border of a precipice. Only recently, while listening to a lecture on insanity by one of the most

noted neurologists in New York, he stated an experience of his own, and said that once while visiting some romantic scenery in the great West, he desired to look down a deep precipice. He laid down flat on his face close to the edge of it and gazed into the depths below. To his utter amazement he was seized with a desire to throw himself down the abyss, and lost the power of restraint. He called vigorously to his friends near by to drag him back, and this alone saved him from the deed. While, however, such impulses are frequent, we believe they do not trouble the peace of mind of the majority. Such as have them should strengthen their nervous systems by culture, strengthen their wills and take good care of their brains. —*Herald of Health*.

THE BEST REMEDY.—Those who are afraid of epidemic diseases may feel comforted on hearing that one of the best protective measures they can resort to is a very simple one—the use of soap and water. An eminent physician says: "It is worth while for common people to learn that 50,000 typhus germs will thrive in the circumference of a pinhead or a visible globule. It is worth while for them to note that these germs may be desiccated and be borne like thistle seeds every where, and, like demoniacal possessions, may jump noiselessly down any throat. But there are certain things spores cannot stand, according to the latest ascertained results of science. A water temperature 120 degrees boils them to death, and soap chemically poisons them. Here sanitary and microscopic science come together. Spores thrive in low ground and under low conditions of life. For redemption, fly to hot water and soap, ye who live in danger of malarial poisoning. Hot water is sanitary; soap is more sanitary. Fight typhus, small-pox, yellow fever and ague with soap. Soap is a Board of Health." "Cleanliness is next to godliness," and so far as physical health goes, far in advance of what passes current for godliness in this wicked world. But, as a matter of fact, it is a poor kind of godliness that does not make people cleaner as well as better. Daily contact with soap and water will help wonderfully in properly regulating the habits of everyday life.

A NEW MODE OF BURIAL.—At the recent general assembly of cement manufacturers at Berlin, Dr. Fruhling described a new application of cement. He explained that it would be easy to transform corpses into stone mummies by the use of Portland cement, that substance when hardened not in any way indicating the organic changes going on within it. He further illustrated the subject by describing various industrial uses of lime as a preventive of decomposition. The cement in hardening takes an accurate cast of the features which it incloses, thus allowing of their exact reproduction after the lapse of centuries. It is suggested to use coffins of rectangular shape, it being further considered by Dr. Fruhling that underground sepulture is needless, as the coffins soon become practically masses of stone, and can therefore be built into pyramids.

COPPER AND LEAD IN FOOD.—A. Gautier shows that copper is little calculated to produce mortal results. The solubility of most of its salts, their marked color, nauseating taste, and emetic action give at once warning. The salts of lead, on the contrary, have no pronounced taste, or are even sweetish. They are in general colorless. If introduced into the system, there is no alarming effect until the nervous centers, the liver, and the blood have become interpenetrated with the poison. All foods sold in tins, especially if of a fatty nature, public water supplies, wines, beers, effervescing drinks, the glaze of earthenware, enamels, and especially culinary utensils lined with tin, may introduce lead into the system.
